PREFACE

Texas A&M University (TAMU) was subcontracted by the National Marine Fisheries Service (NMFS) Galveston Laboratory to assist in a study on sea turtle utilization of and movement within inshore habitats adjacent to South Padre Island, Texas. This subcontract was part of a larger contract between NMFS and the U.S. Army Corps of Engineers to assess potential impact of channel dredging operations on sea turtles. The University was mandated by NMFS to capture sea turtles within Brazos Santiago Pass and lower Laguna Madre areas for tagging and tracking purposes. Using location data provided by the NMFS tracking program, TAMU characterized environmental attributes of various habitats occupied by tagged turtles. This report summarizes results of sea turtle capture operations and habitat characterization activities conducted by TAMU during April through September 1991. Results of additional capture activities, conducted through December 1991, also are reported herein to further characterize seasonal occurrence of sea turtles in the South Padre Island study area.

Introduction

Concern about recovery and management of endangered sea turtle stocks of the Gulf of Mexico was addressed by a 1989 Minerals Management Service Workshop on Marine Mammals and Turtles in the Gulf of Mexico. Draft proceedings from this workshop and a Marine Turtle Habitat Plan developed by National Marine Fisheries Service (NMFS) sea turtle biologists (Thompson et al. 1990) both recommend characterization of turtle habitat as the most appropriate research approach to recovery and management of Gulf sea turtle stocks. Mandates with the highest priority for optimizing research on these stocks (Thompson et al. 1990) included identifying and characterizing habitats of Kemp's ridley (*Lepidochelys kempi*) and green sea turtles (*Chelonia mydas*). Texas waters provide critical habitat for both these species. Mark-recapture and stranding data collected by NMFS indicate inshore waters from eastern Texas to the Mississippi Sound are currently crucial habitat for all size classes of Kemp's ridley except the pelagic stage. Another critical habitat that harbors green turtles includes seagrass beds in Texas' Laguna Madre. Numerous sightings of sea turtles by the public at jetties and channel entrances along the central and south Texas coast during summer months suggest these areas also serve as development habitats for juvenile and subadult sea turtles.

Several activities have been identified as sources of mortality to sea turtles in inshore waters (Magnusom et al. 1990). Most notable among these are channel dredging operations by the U.S. Army Corps of Engineers (COE). Specific COE dredging activities posing risks to sea turtles include maintenance dredging of intracoastal waterways and about 45 ship channels in the Gulf and Atlantic, disposal of dredged materials, beach nourishment, and marine construction (Thompson et al. 1990).

Resolution of sea turtle/industry conflicts such as channel dredging and implementation of proper management of existing stocks are severely compromised by the paucity of quantitative data on natural history of sea turtles, particularly those in the northwestern Gulf. A Sea Turtle Conservation Amendment developed by Senator Howell Heflin from Alabama called, in part, for information on: "estimates of the status, size, age structure and where possible sex structure...and the distribution and concentration of each of the relevant species of sea turtles, in the waters of the U.S., Mexico...during both the migratory and reproductive phases of their lives" (news release from the Office of U.S. Sen. Howell Heflin of Alabama, July 12, 1988). A Regional Sea Turtle Review Workshop dealing with turtle stocks of the South Atlantic and Gulf of Mexico has recommended that NOAA "..... should assist with gathering crucially important data on distribution and abundance of all sea turtle species in state nearshore and inshore waters" (October 14, 1988, letter from Messrs. Ralph Rayburn and Michael Weber, co-chairmen, Regional Sea Turtle Review Workshop, to Dr. Joseph Angelovic, Director of NMFS' Southeast Region). An even larger information gap exists on species composition, size distribution, spatial and temporal abundance, habitat preference, feeding grounds and nesting activity of sea turtles in nearshore and estuarine waters of Texas. Reduced abundances, cryptic habitats, and smaller size of the immature stages of sea turtles in nearshore and estuarine waters together with poor water clarity in these areas render visual observations and acquisition of natural history data on live turtles in the northwestern Gulf very difficult. Consequently, netting and tag-recapture operations in selected Texas bays could provide essential data on abundance and distribution of live turtles in these bays.

Risks associated with COE dredging activities were the subject of collaborative research conducted by Texas A&M University (TAMU) and NMFS personnel during Summer 1991 on green and loggerhead turtles inhabiting seagrass, jetty and channel environments of the Brazos Santiago Pass and lower Laguna Madre adjacent to South Padre Island, Texas. Five turtles captured in TAMU's netting program were provided to NMFS who equipped them with radio and sonic transmitters in order to define behavior and movement in the South Padre Island area. Daily location data generated by NMFS' tracking program were used by TAMU to characterize habitats frequented by these tagged turtles. This report summarizes results of TAMU's sea turtle capture operations in the South Padre Island study area and the characterization of habitats utilized by these turtles.

Study Area and Methods

Study Area

Turtle capture and habitat characterization were conducted in Brazos Santiago Pass and lower Laguna Madre habitats adjacent to South Padre Island, Texas during April-December 1991 (Fig. 1). This study area was partitioned into three, relatively discrete sea turtle capture/habitat characterization sites (Figs. 2, 3 and 4). These sites are described below.

Brazos Santiago Pass Site: This site consists of the Brazos Santiago Pass and adjacent North and South Jetties (Fig. 2). Brazos Santiago Pass is a narrow (92 m wide) channel between the south end of South Padre Island and the north end of Brazos Island that has a maximum depth of 11.6 m. The North and South Jetties are 1.5 km long granite mound structures bordering the

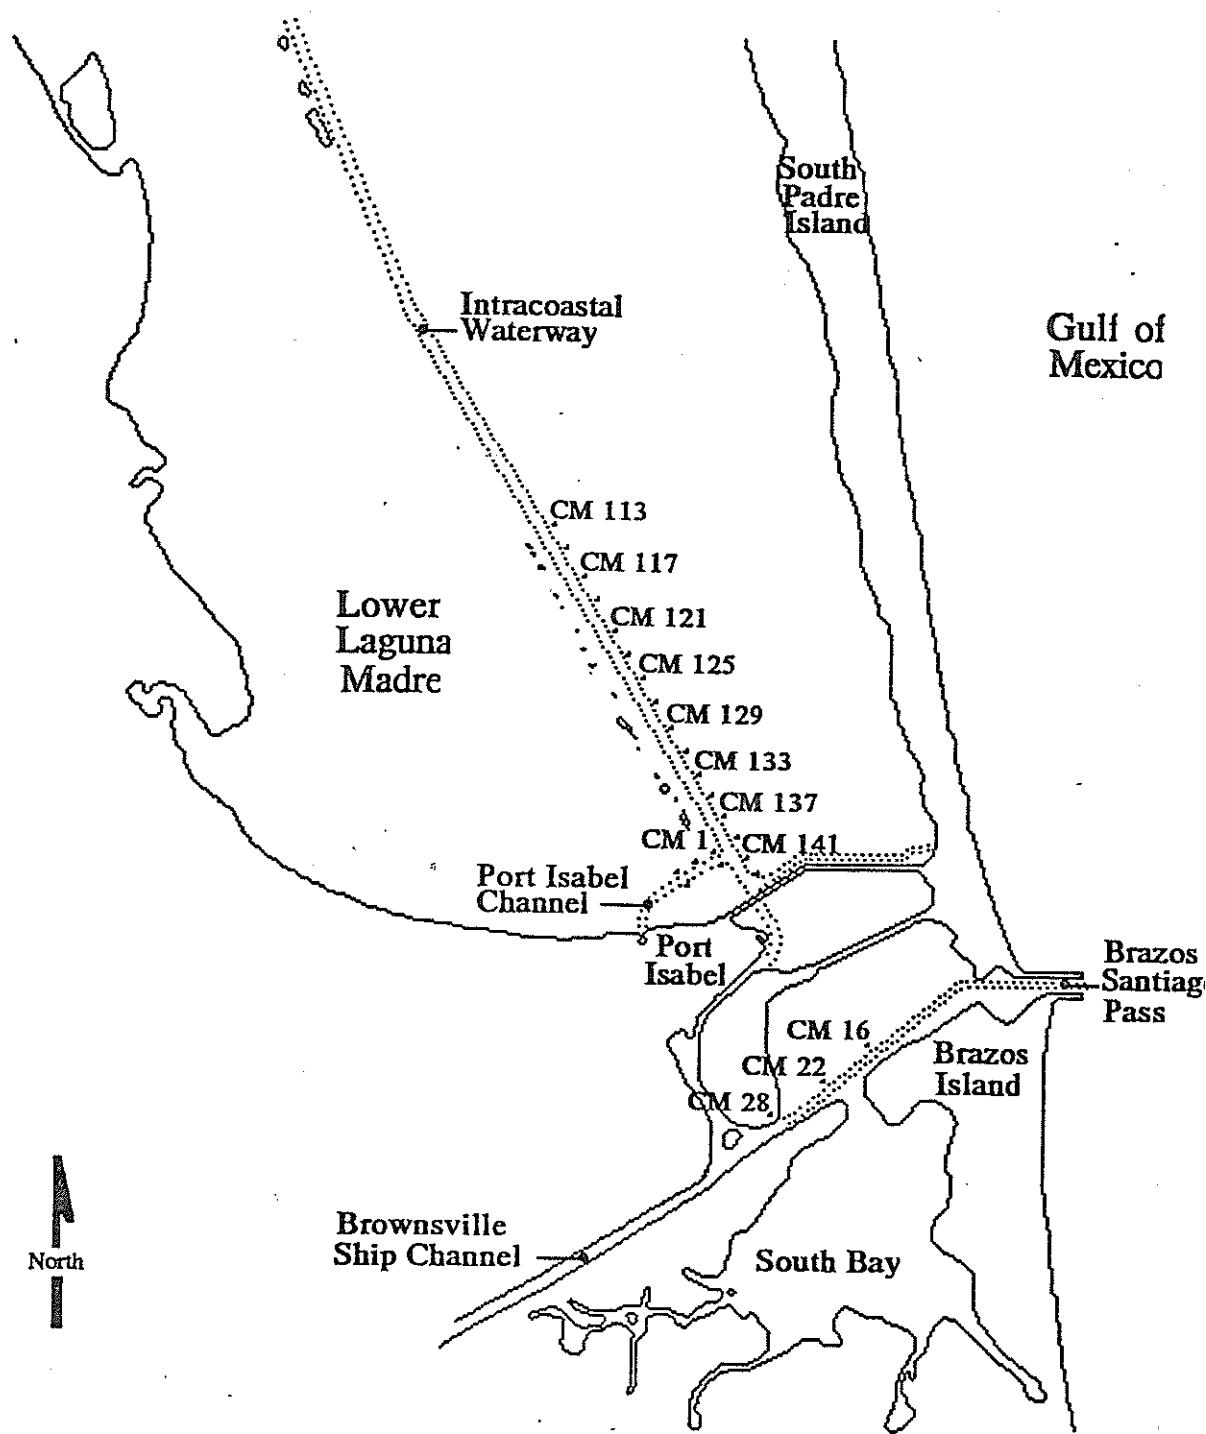

Figure 1. Map of South Padre Island study area. CM denotes channel markers.

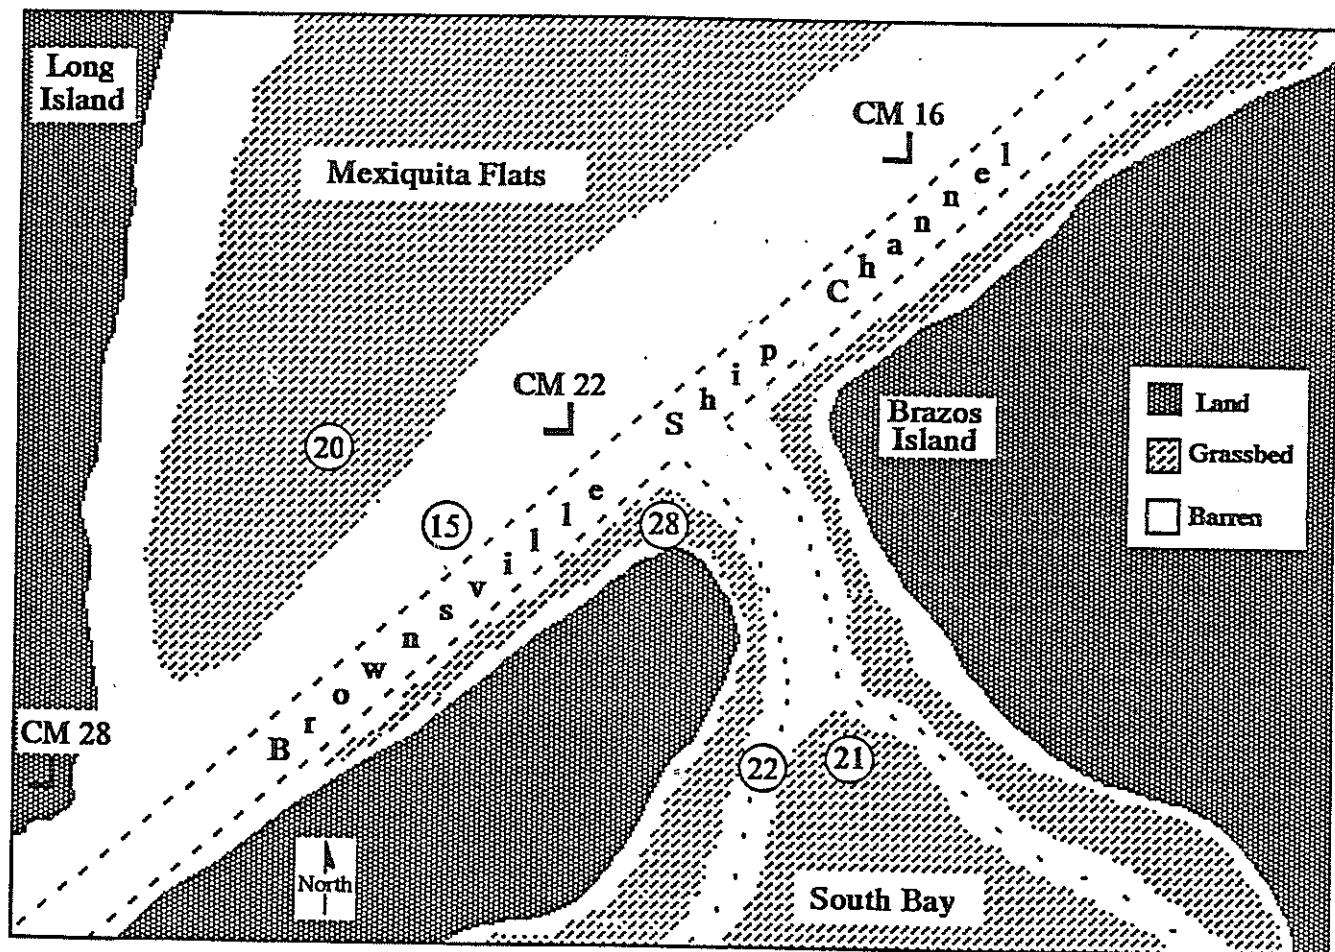

Figure 3. South Bay/Mexiquita Flats habitats and sampling stations (#).

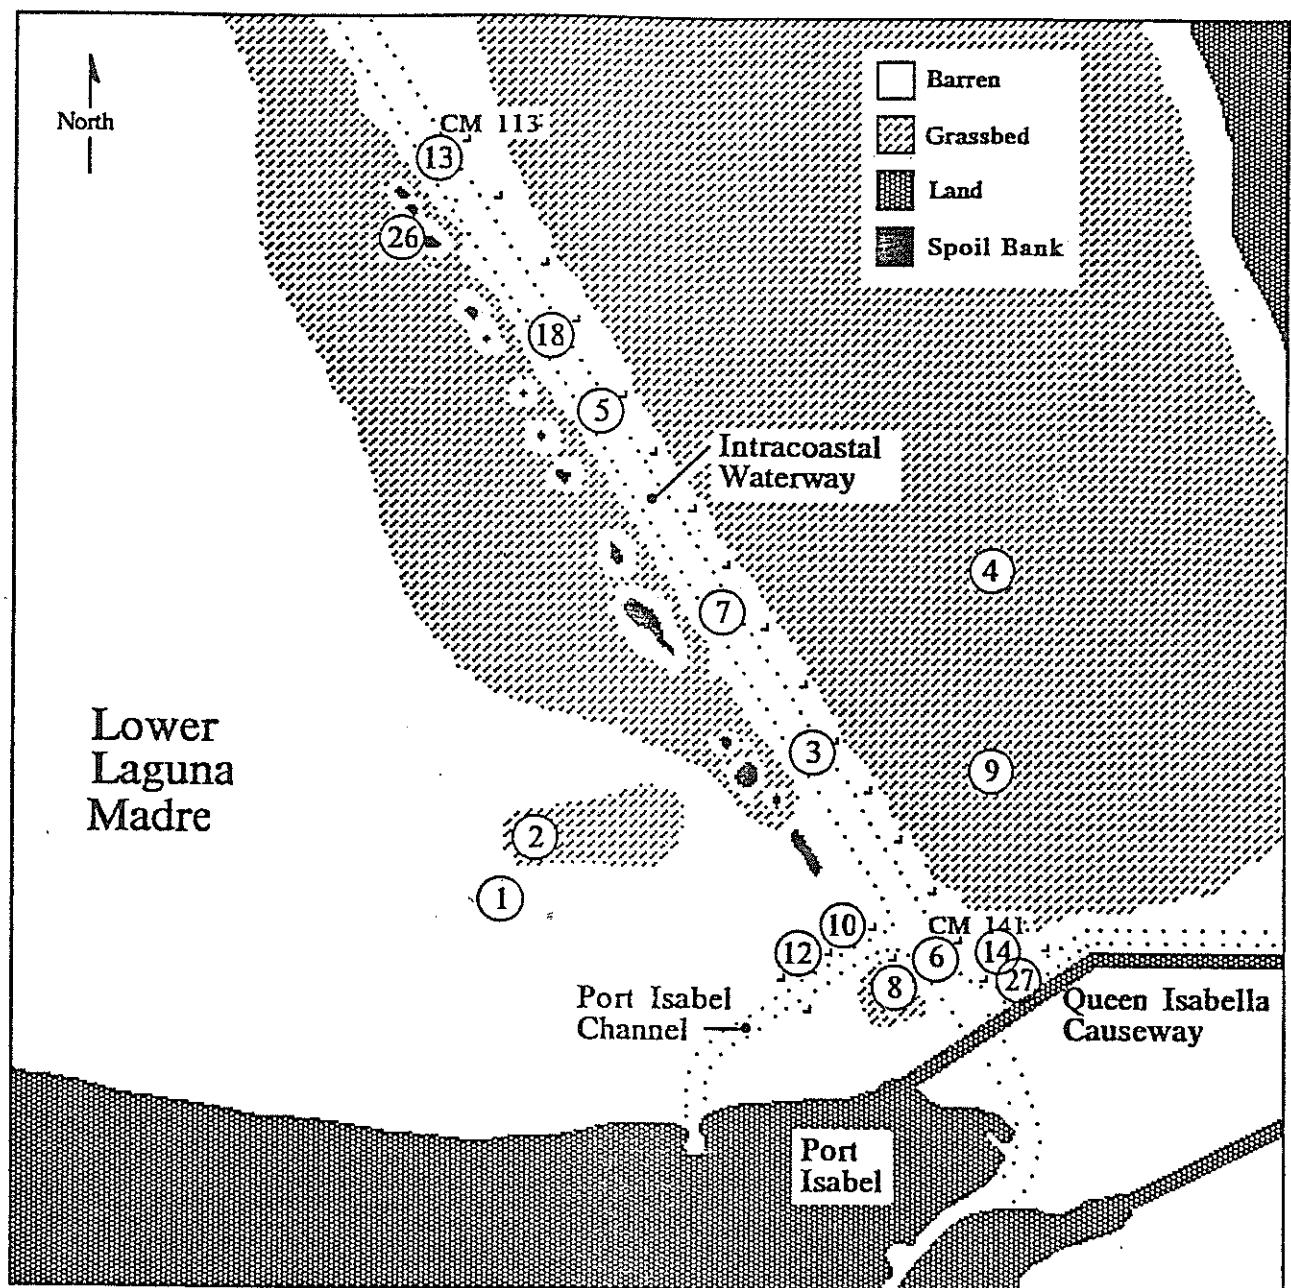

Figure 4. Lower Laguna Madre habitats and sampling stations (Ⓐ).

north and south sides of the Brazos Santiago Pass at its entrance into the Gulf of Mexico. Shallow, relatively flat cove areas with a hard sand bottom and average depth of 2.1 m are located inside the west end of each jetty. These habitats support various species and concentrations of algae. Seven sampling stations (5 barren-bottom, 2 channel) were located within the jetty site (Table 1), with these locations based on: 1) NMFS' mandate that initial sea turtle capture and characterization efforts be conducted at Brazos Santiago Pass; 2) habitats exhibiting certain conditions (depth, minimal obstructions) that rendered them compatible for netting; and 3) a change in habitats occupied by turtles over time.

South Bay/Mexiquita Flats Site: The South Bay/Mexiquita Flats site consists of grassbed and channel habitats along the easternmost reaches of the Brownsville Ship Channel (BSC) between Channel Markers 28 and 16 (Fig. 3). The channel habitat of the BSC is 2.25 km long, 61.0 m wide with an average maximum depth of 11.0 m and is bordered on the south and north by seagrass habitats of South Bay and Mexiquita Flats, respectively. The BSC channel substrate consisted of mud with varying portions of sand, clay, and silt and extended to grassbed habitat at a depth of 1.8 m. Grassbed habitats in South Bay and Mexiquita Flats were less than 1.5 m deep and consisted of a silt and hard sand substrate. This site contained five sampling stations (3 grassbeds, 1 channel, 1 barren-bottom - Table 1).

Lower Laguna Madre Site: The lower Laguna Madre site encompassed the lower Laguna Madre from Intracoastal Waterway (IWW) Channel Marker 113 south to the Queen Isabella Causeway (Fig. 4). This site contains the IWW channel and adjacent grassbed and barren-

	27	N of and adjacent to causeway 100 m E of IWW channel	Barren bottom	(26 04.37'N/97 11.8'

bottom (hard bottom, mudflat and dredge spoil) habitats. The IWW channel habitat incorporates an area 6.9 km long and 38.1 m wide with an average depth of 3.7 m. The channel substrate ranged from a deep (\geq 1.2 m) soft silt at the north end to hard sand/shell hash at the south end. Six sampling stations were located in this channel habitat (Table 1).

The southern end of the Laguna Madre adjacent to the IWW was generally less than 1:2 m deep and composed of scattered barren-bottom and grassbed habitats (Fig. 4). The substrate in these habitats ranged from mud with varying proportions of sand and clay to hard sand that supported seagrasses. Ten sampling stations (5 grassbeds, 3 hard bottom and 2 dredge spoils) were located among these habitats (Table 1).

Sea Turtle Capture and Related Activities

Entanglement Netting: Turtle capture was accomplished with 91.5 m long entanglement nets of different depth and mesh size specifications deployed in two configurations. This experimental design increased the array of turtles and habitats that could be sampled. These nets were 3.7 m deep with 12.7 cm bar mesh of #9 twisted nylon or 4.9 m deep with 25.4 cm bar mesh of #9 twisted nylon. Shallow coves of Brazos Santiago Pass, grassbeds and channels of the lower Laguna Madre and South Bay/Mexiquita Flats were sampled during the day with one to four stationary entanglement nets (of similar or mixed specifications) set adjacent to one another for 8 to 12 hours (Fig. 5). Sampling at the deeper, jetty habitat was modified to a more active capture method of encircling turtles with entanglement nets. The encircling technique was attempted only when a turtle targeted for capture displayed certain behavioral traits. These traits

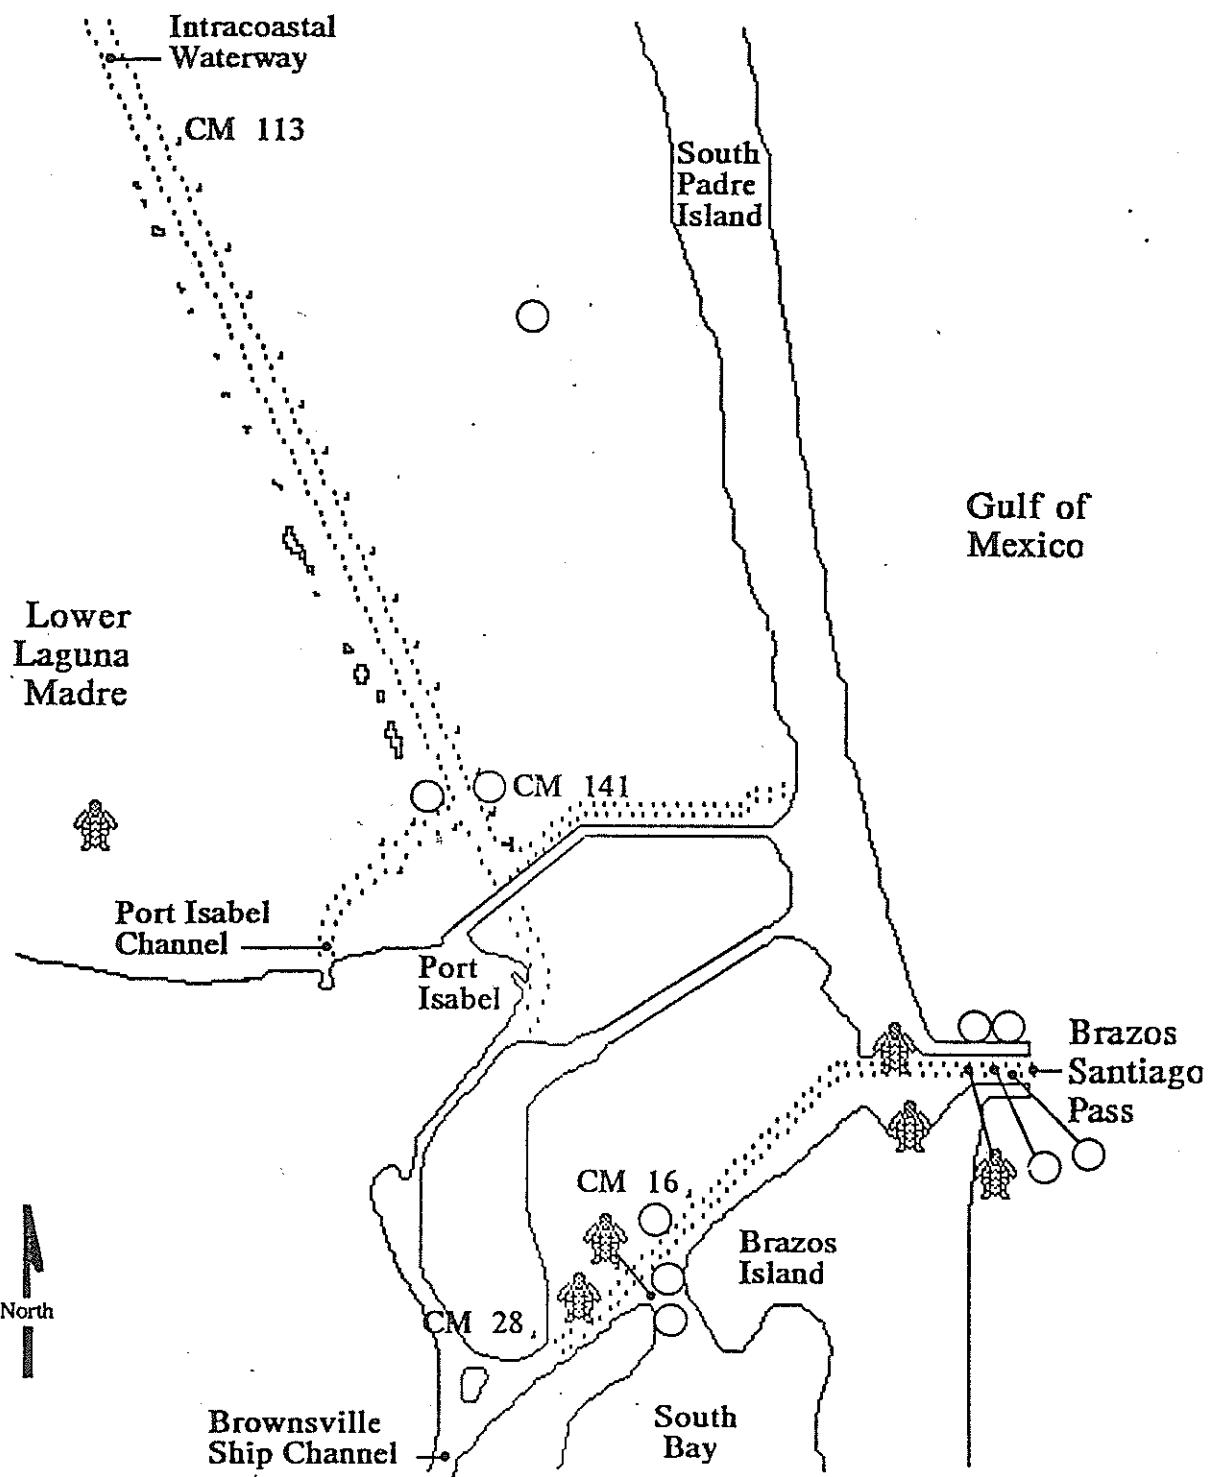

Figure 5. Entanglement netting deployment (○) and sea turtle capture locations (▲) within the South Padre Island study site.

included: 1) exhibiting a sustained (\geq 30 minutes) pattern of surfacing and sounding which became predictable (i.e., surfacing to breathe every 12 minutes); and 2) surfacing occurred no more than 10 m from and along a very limited (\leq 30 m) length of the jetty. Once these traits became well established, the encircling set began approximately 1 minute prior to the predicted surfacing time by securing one end of the net to the jetty and quickly encircling the expected surfacing spot with the remaining net deployed from a boat. The net was brought to the jetty to create a "semi-circle" of netting around the turtle. Divers entered the encircled area to close off any escape route and to catch or maneuver a turtle into the net. The rocky bottom along the jetties often fouled the net and made turtle capture in this habitat difficult.

Tagging Activities: Immediately following capture, all turtles were transported to the University of Texas' Pan American Laboratory on South Padre Island where they were held for 24 hr before being tagged and released. All turtles were measured, photographed and tagged at the lab. Straight line carapace length and width were measured with a forester's calipers. Over-the-curve carapace length and width were measured with nylon twine and a forester's caliper. All measurements were made to the nearest 0.1 cm. Turtles were then photographed with a 35-mm camera and placed in a 3.0-m diameter fiberglass holding tank. The following day the turtles were tagged with one monel flipper tag (provided by NMFS/Miami), on the trailing edge of each fore flipper and released at the same location as captured. Tagging data were submitted to NMFS (Miami) on two data forms entitled, NMFS/SEFC Marine Turtle Tagging Data (Rehabilitated, Netted or other Release) and NMFS/SEFC Marine Turtle Tagged/Recapture Data.

Fecal Pellet Analysis: Periodic checks of each turtle's condition were made during the 24-hr holding period, and fecal samples were collected from the tanks. All fecal samples were preserved in 10% formalin, labelled and held for laboratory analysis. Each fecal pellet sample was pulse blended to an even consistency in the laboratory. These contents were then poured into a #35 sieve and rinsed with seawater. Three samples were removed from each fecal solution with a spoon and then observed under a compound scope to identify particulate plant and algae matter to the lowest possible taxon.

Visual Observations: Visual sightings were conducted along the North and South Jetties at Brazos Santiago Pass to aid in turtle capture and habitat characterization efforts. These sighting efforts helped to locate turtles and define the habitats they frequented. Random observations were made by 2-5 individuals surveying the jetties on random days throughout the study period. Date, time, location, and species were recorded each time a turtle was sighted.

Habitat Characterization

Five turtles captured during netting activities across the study area were provided to NMFS personnel who equipped them with radio and sonic tags (Table 2). These turtles were released in the same area in which they were captured, and were later tracked by NMFS personnel. Data from NMFS tracking efforts were used by TAMU personnel to pinpoint habitats occupied by the tracked turtles. These data were used to identify 28 stations (9 channel, 11 barren-bottom and 8 grassbed sites) whose habitat attributes were characterized from 1 July through 25 October 1991 (Table 1).

On-site habitat characterization efforts (Table 3) consisted of: 1) hydrological monitoring; 2) SCUBA surveys; and 3) trawl surveys. A description of these characterization techniques follows.

Hydrological Monitoring: Surface and bottom measurements (depth permitting) were taken whenever a station was occupied to characterize water temperature, salinity and conductivity. Water temperature (to the nearest 0.1° C), salinity (to the nearest 0.1 ppt) and conductivity (to the nearest 0.1 mmhos/cm) were measured with a Beckman Instrument Company Conductivity-Salinity-Temperature meter.

SCUBA Surveys: Each station was initially characterized by a SCUBA survey to describe habitat and potential food sources available to sea turtles. This survey consisted of several tasks (listed in order of performance): 1) subsurface visual observations; 2) quantitative transects; 3) sample quadrates (flora and fauna); and 4) sediment core samples.

Subsurface visual observations were conducted by two to four SCUBA divers to describe the habitat (i.e. channel, grassbed, barren-bottom) and assess prevailing water conditions (i.e. visibility, current). This assessment dictated which characterization tasks could be conducted and the number of samples taken for each task.

Quantitative transects were deployed to characterize the availability of forage species. The ability to conduct transect sampling was dependent on visibility. At stations with visibility ≥ 1 m, three 25-m transect lines (weighted 0.6-cm nylon line) were laid parallel to one another approximately 20 m apart. Transects were visually surveyed by two SCUBA divers swimming

down the line (one on each side), with each diver recording all organisms and habitat characteristics along a 1-m wide corridor.

Quadrates were utilized to characterize prey availability, vegetative cover and sediment texture. After completing the swimming transects, a 1 m² quadrate (1.9-cm diameter PVC) was randomly placed on each transect line (if no transect line, quadrates were randomly placed within the station) and visually surveyed by one or two SCUBA divers recording all organisms and sediment types within the quadrate. Next one 0.25 m² quadrate (1.9-cm diameter PVC) was placed inside each 1 m² quadrate, and its contents were recorded and collected. Algae and seagrasses within the 0.25 m² quadrate were cut approximately 2.54 cm above the sediment, bagged, preserved in 10% formalin and returned to the laboratory for analysis. All demersal organisms within the 0.25 m² quadrate also were recorded, collected, preserved in 10% formalin and returned to the laboratory. The number of quadrates deployed at a station varied with habitat type. One set (i.e., 1 m² and 0.25 m²) of quadrates was sampled at channel and barren-bottom stations. Three sets of quadrates were sampled at all grassbed stations. Six additional replicate quadrates (vegetation analysis only) were taken within the South Bay/Mexiquita Flats site to verify the percent composition found in initial quadrates. Nine quadrates were used to sample the zonation (boulders, rubble, sand) at jetty stations. Three sets of quadrate samples were taken from each jetty transect by SCUBA divers swimming down the transect 10 kicks and randomly placing the quadrate on the line.

Each vegetation sample was emptied into a #35 sieve, rinsed with seawater, and separated to the lowest possible taxon. Separated taxa were placed in paper bags which were labelled and stapled shut. Each paper bag was dried in an oven for approximately 40 hr at 82° C. After

drying, each bag and its contents were weighed (to the nearest 0.01 g) and the mass of an empty, stapled bag was subtracted. The resulting weight was used as the dry mass for each species.

Following quadrate sampling, cores were taken for the purpose of analyzing sediment texture. One 15.2-cm long x 3.8-cm diameter core (PVC) sample was taken by a SCUBA diver at each station. All core samples were labeled, frozen and held for analysis. This analysis followed procedures developed by Folk (1965) and began with a representative subsample from each sediment core sample being placed in a dispersant solution and shaken overnight. Once dispersed, it was wet-sieved through a standard 62 μ (U.S. #230) stainless steel sieve (4ϕ) with distilled water. The sand fraction ($> 4 \phi$) was dried, weighed, disaggregated and Ro-Tapped (15 min) through a 0.5 ϕ interval stack of eleven brass sieves (-10 ϕ to 4 ϕ). The weight of each 0.5 ϕ interval was determined. The silt-clay fraction ($> 4 \phi$) was collected in 1000 ml columns filled to capacity with distilled water and pipetted at depths and times after stirring to 0.5 ϕ intervals.

Trawl Survey: Three replicate tows of a 6.1-m otter trawl having 1.9-cm bar mesh netting throughout and a 0.6-cm bar mesh cod end were conducted at respective sampling stations to characterize food item availability in channel, grassbed and barren-bottom sites. Trawls were towed for 5 minutes at all sites except those in grassbed habitats. One minute tows were conducted at these sites to reduce clogging of the trawl with vegetation. Each trawl sample was sorted, identified to the lowest possible taxon, measured (only fish and commercially-important

shrimp and crabs), counted and recorded in the field. All unidentified organisms were returned to the lab for analysis.

Results

Sea Turtle Capture and Related Activities

Turtle capture activities were conducted from 12 April - 12 December 1991, during which time the Brazos Santiago Pass, South Bay/Mexiquita Flats, and lower Laguna Madre sites were netted 29, 15 and 6 days, respectively (Table 4). This netting effort was conducted at 16 locations across the 3 sites as follows: 7 in Brazos Santiago Pass, 5 in South Bay/Mexiquita Flats and 4 in the lower Laguna Madre (Fig. 5).

Daily capture effort expended at each site is presented in Table 4. Over 905 netting hours were generated during 90 net sets. Total netting hours ranged from 118 at lower Laguna Madre habitats to 427 at Brazos Santiago Pass (Table 5). These net-sets were supplemented by 11 encirclement attempts made over 7 days at Brazos Santiago Pass habitats.

Capture efforts produced 19 sea turtles: 17 in entanglement nets and 2 by incidental means (Table 2). These turtles consisted of 4 green turtles from the Brazos Santiago Pass site, 12 green turtles from the South Bay/Mexiquita Flats site and 1 loggerhead from the lower Laguna Madre site. Five turtles were captured in 3.7-m deep nets and the remaining 12 in 4.9-m deep nets. Included among these captures were one recapture from the Brazos Santiago Pass site and another recapture from the South Bay/Mexiquita Flats site. Incidental captures included two green turtles from the North Jetty at Brazos Santiago Pass, where one was foul hooked by a fisherman and the other hand-captured by TAMU.

<u>Encirclement</u>	11	1
<u>Incidental</u>		2

* - capture of Caretta caretta

Turtle captures occurred from 12 April - 22 November 1991 (Table 2). Monthly total captures ranged from 0 in December to 5 during both October and November. The latter two months each yielded one multiple catch of three turtles in one day. Over one half of all netted turtles were captured between 1100 - 1300 hrs.

Straight carapace length (SCL) of the 17 green turtles captured in the study area ranged from 28.6 to 58.9 cm (Table 2 and Fig. 6). All green turtles captured from the Brazos Santiago Pass site (jetties) exhibited a SCL < 40 cm while those from the South Bay/Mexiquita Flats site (grassbeds/channels) were always > 40 cm SCL (Fig. 6). The only loggerhead captured was 72.5 cm SCL.

Visual Observations: Visual observations were conducted from 3 July - 12 December 1991 in an attempt to locate sea turtles utilizing Brazos Santiago Pass habitats. Table 6 summarizes results of these visual observations plus incidental turtle sightings made during netting operations. Two-hundred-eighty-one sightings of a possible 106 individual turtles were recorded during 27 days of observation effort. An additional nine sightings of a suspected seven turtles were recorded from incidental observations. Ninety seven turtles were observed along the jetty proper while nine turtles were seen in adjacent coves. Turtles were sighted monthly along the jetty proper; however, after an incidental sighting in May, turtles were not observed in the coves again until October. All of the sightings were green turtles except for three individuals that could not be identified. One of the most frequently observed and easily identifiable turtles was a 34.2-cm SCL green turtle initially captured on 15 July, tagged (flipper tags-QQC707/NNZ612

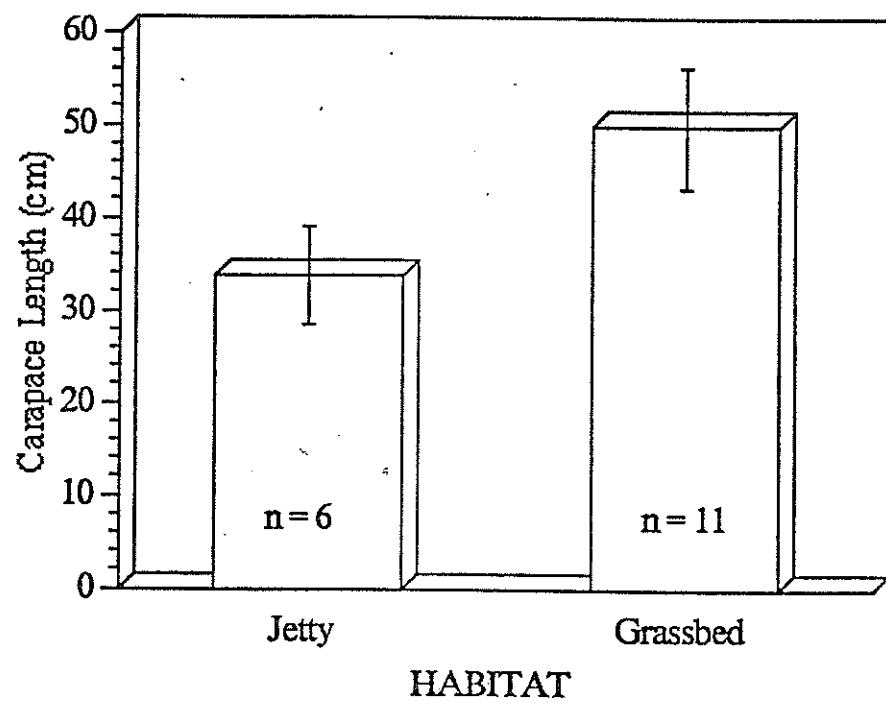

Figure 6. Mean carapace length (cm) of green sea turtles (*Chelonia mydas*) netted at jetty and grassbed habitats. Vertical bar denotes standard deviation.

Table 6. Sightings of green (*Chelonia mydas*) and unidentified sea turtle species within the South Padre Island study area during May-December 1991.

and radio/sonic tagged) and released (Table 2) within the Brazos Santiago Pass (Station 11). This turtle was observed along the Gulf side of the North Jetty (Stations 17 and 19) at least monthly during August through October.

Habitat Characterization

Hydrological Monitoring: Water temperature (surface) across the entire study area during the characterization period (July - September) ranged from 25.0° C at Brazos Santiago Pass site on 22 July to 33.0° C at both Brazos Santiago Pass and South Bay/Mexiquita Flat sites on 5 - 6 August (Appendix Table 1). Homogenous readings averaging 28.7°C characterized water temperatures throughout the study area. The last week of July exhibited the highest degree of temperature fluctuation, with an average temperature of 26.8°C across the study area.

Surface salinity readings across the study area were relatively stable (Appendix Table 1). Values ranging from 33 ppt at Brazos Santiago Pass site on 8 September to 37 ppt lower Laguna Madre site on 6 September were indicative of a homogenous salinity regime during the characterization period. The average salinity for the entire study area was 35.3 ppt.

Sediment Analysis: Texture analyses indicated sand contributed the highest percentage of sediment across study area habitats (Table 7). Exceptions to this trend included Station 13, the uppermost station within the IWW, which exhibited the greatest percentage of clay and silt combined, and Station 28, a grassbed habitat in the South Bay/Mexiquita Flats site, having a deep (3 cm) silt layer above sand.

Table 7. Texture composition of sediment from South Padre Island study area stations.

STATION	CORE DEPTH (cm)	% COMPOSITION			SEDIMENT DESCRIPTION
		SAND	SILT	CLAY	
1	0 - 2.5	57.55	20.54	21.91	fine muddy sand w/ shell hash

	3.0 - 8.0	37.98	36.92	25.10	sandy mud

Habitat Utilization: Five radio- and sonic-tagged turtles were tracked by NMFS to identify the utilization of habitats by turtles in the South Padre Island study area. Turtles used for tracking purposes included one loggerhead and four green sea turtles (Table 2). A brief summary of NMFS' tracking results is provided here as an insight to TAMU's selection of habitats which were characterized.

The first turtle to be tagged and tracked was a 72.5-cm SCL loggerhead captured from lower Laguna Madre Station 1 on 26 June. This turtle remained in the lower Laguna Madre throughout the tracking program and primarily utilized IWW channel habitat between Channel Markers 119 and 141 and adjacent grassbeds immediately east of the IWW (Fig. 7). The first green turtle to be tracked was a 34.2-cm SCL individual netted at Brazos Santiago Pass Station 11 on 15 July. After its release, this turtle continued to utilize jetty environs at Brazos Santiago Pass (Fig. 8). This turtle was commonly seen by TAMU observers along the Gulf side of the North Jetty (Stations 17 and 19) through October. The remaining three turtles used in NMFS' tracking program were all green turtles captured at Mexiquita Flats Station 15 (Table 2). The first of these was a 53.6-cm SCL green captured on 26 July that remained in grassbed habitats of Mexiquita Flats and the mouth of South Bay (Fig. 9). A similar habitat utilization pattern was exhibited by a 49.9-cm SCL green captured on 1 August. This turtle restricted its movements to grassbed habitats bordering the Brownsville Ship Channel along Mexiquita Flats and the northeastern shore of Brazos Island (Fig. 10). The last turtle to be tracked was a 54.1-cm SCL green taken on 1 August (Table 2). This individual exhibited the most wide-spread movement among tagged turtles (Fig. 11) by utilizing grassbed and/or channel habitat within all three TAMU study sites.

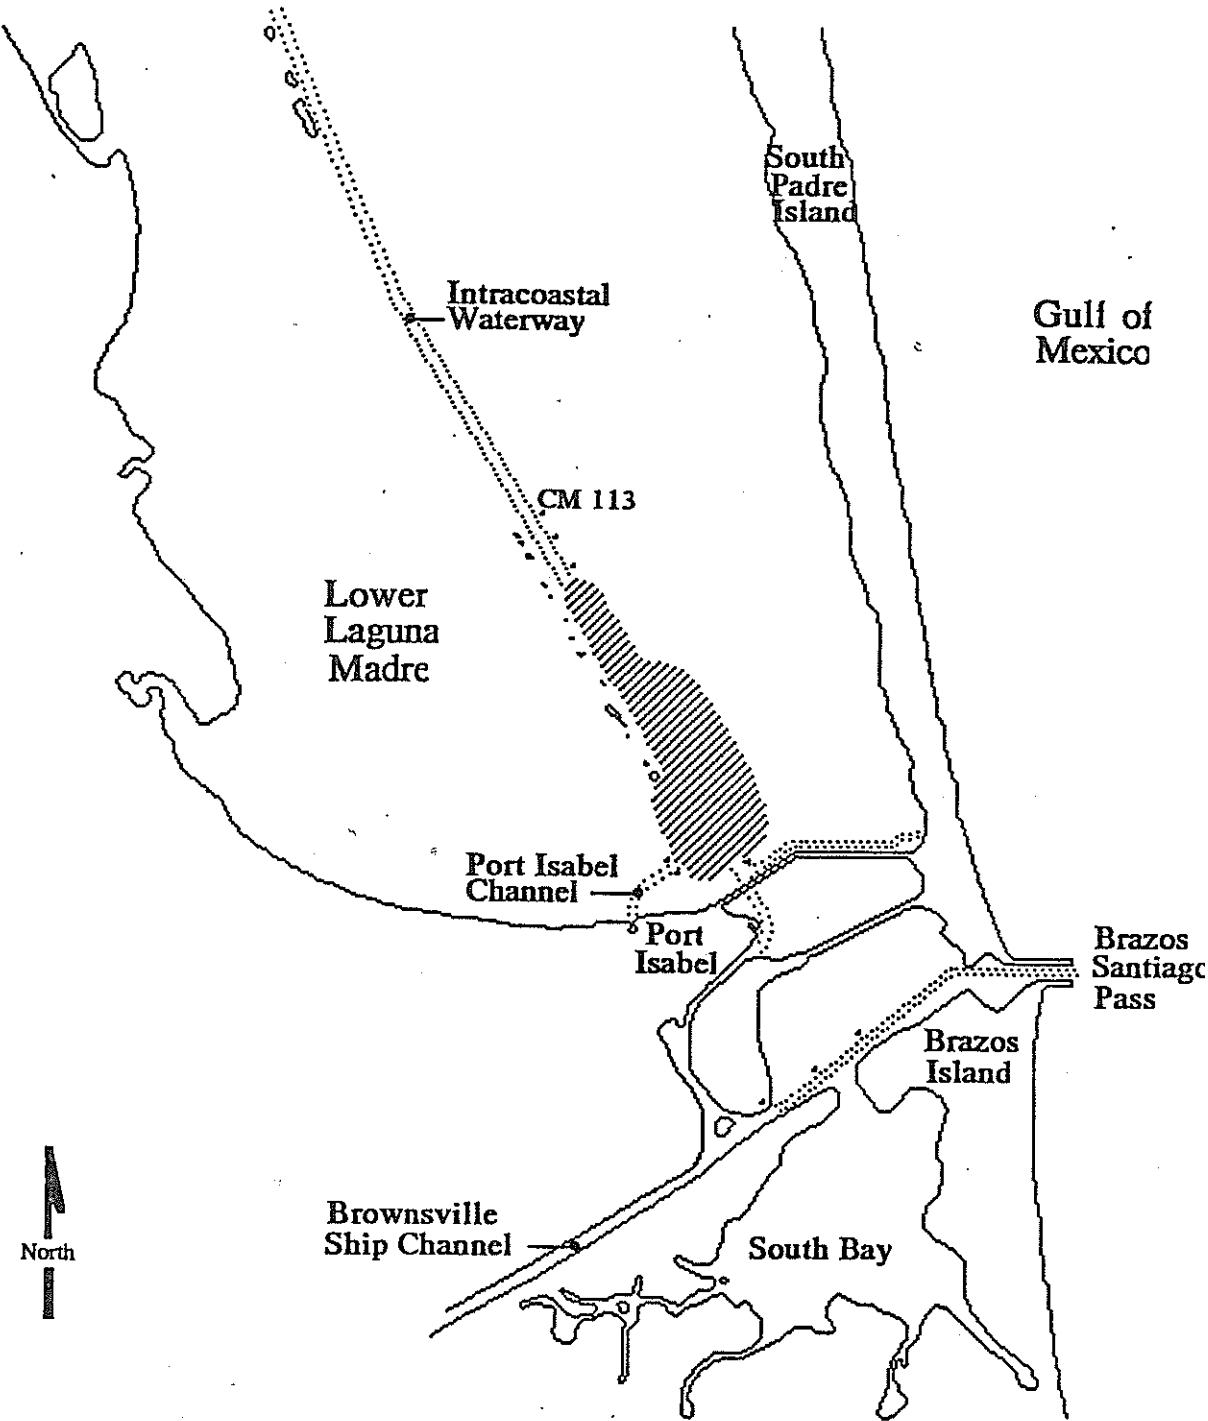

Figure 7. Areal extent of movement by a tagged (QQC 705, QQC 706, NNZ 752) loggerhead (Caretta caretta).

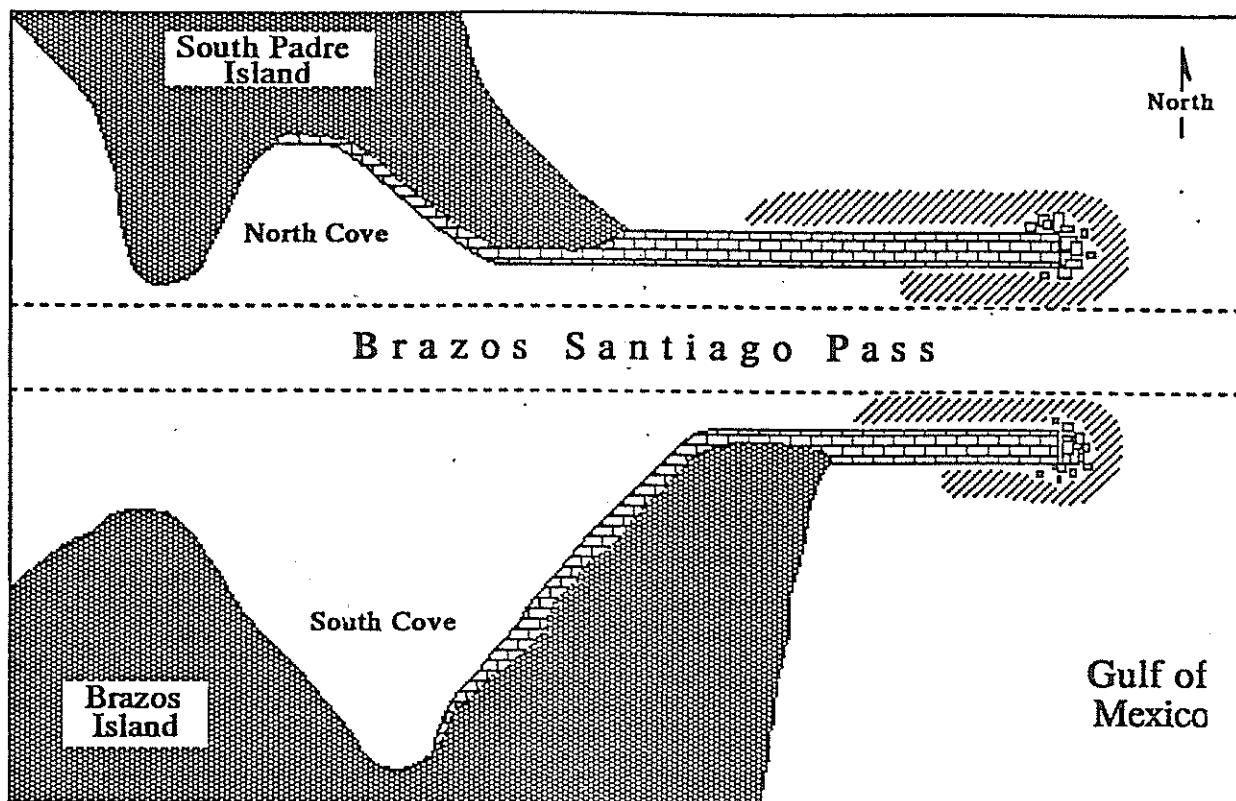

Figure 8. Areal extent of movement by a tagged (QQC 707, NNZ 612) 34.2 cm SCL green turtle (*Chelonia mydas*).

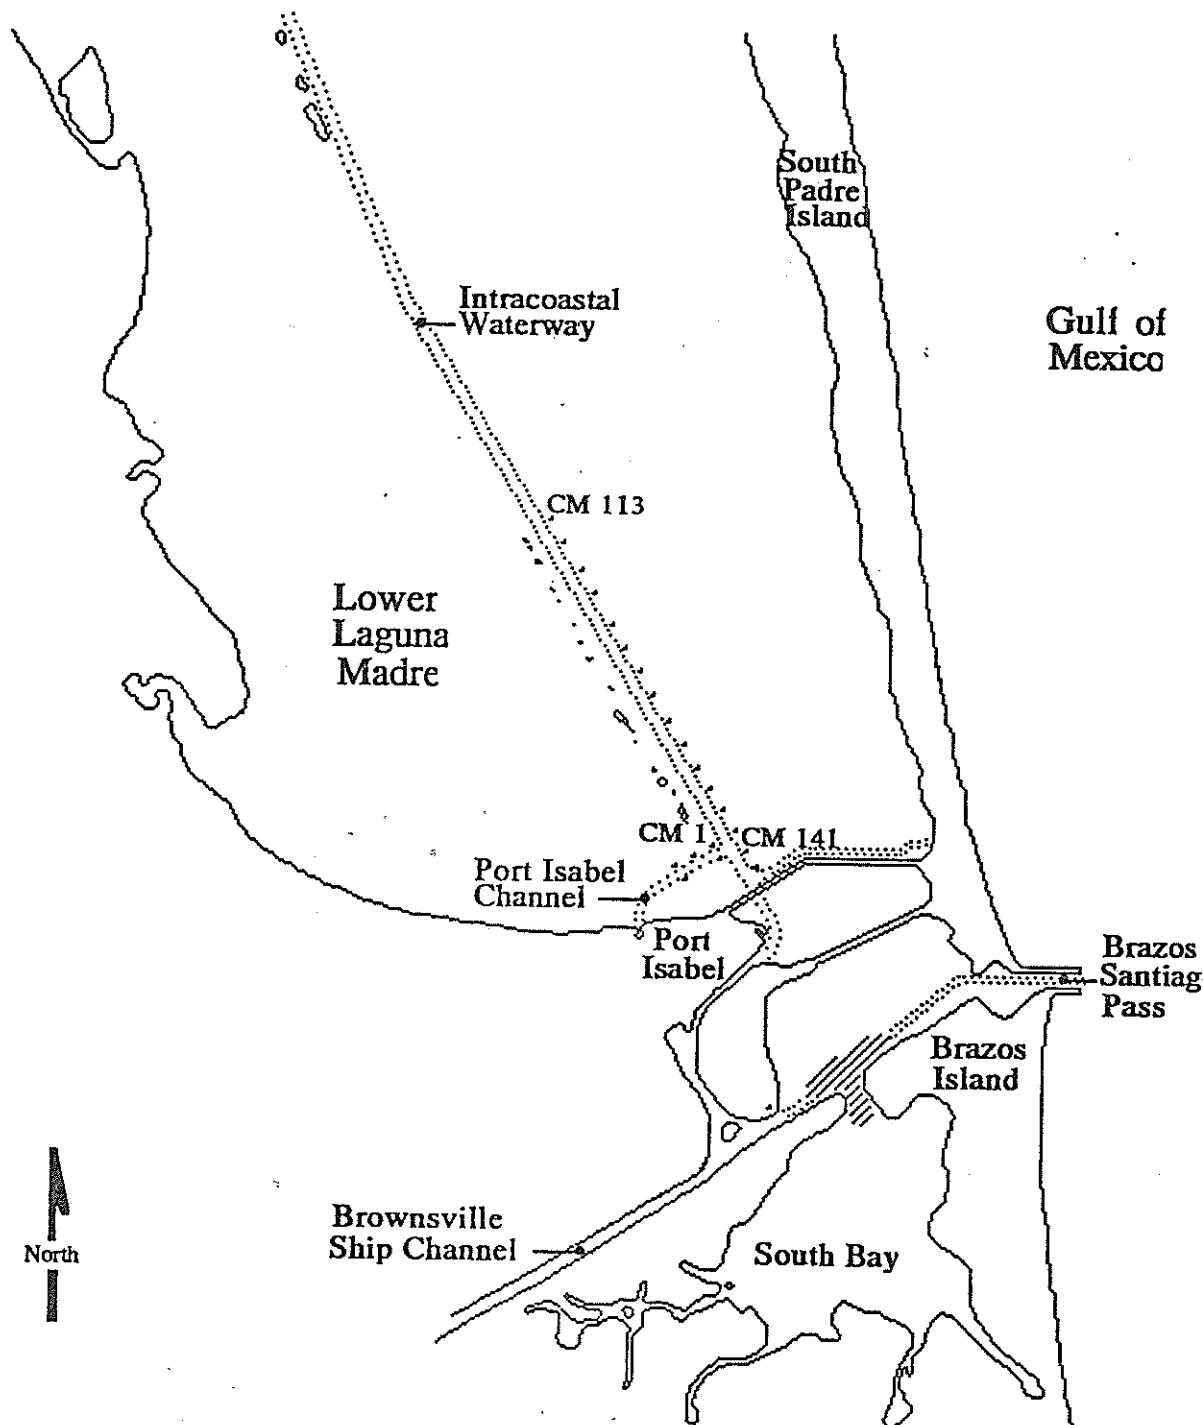

Figure 9. Areal extent of movement by a tagged (QQC 708, QQC 709) 53.6 cm SCL green turtle (*Chelonia mydas*).

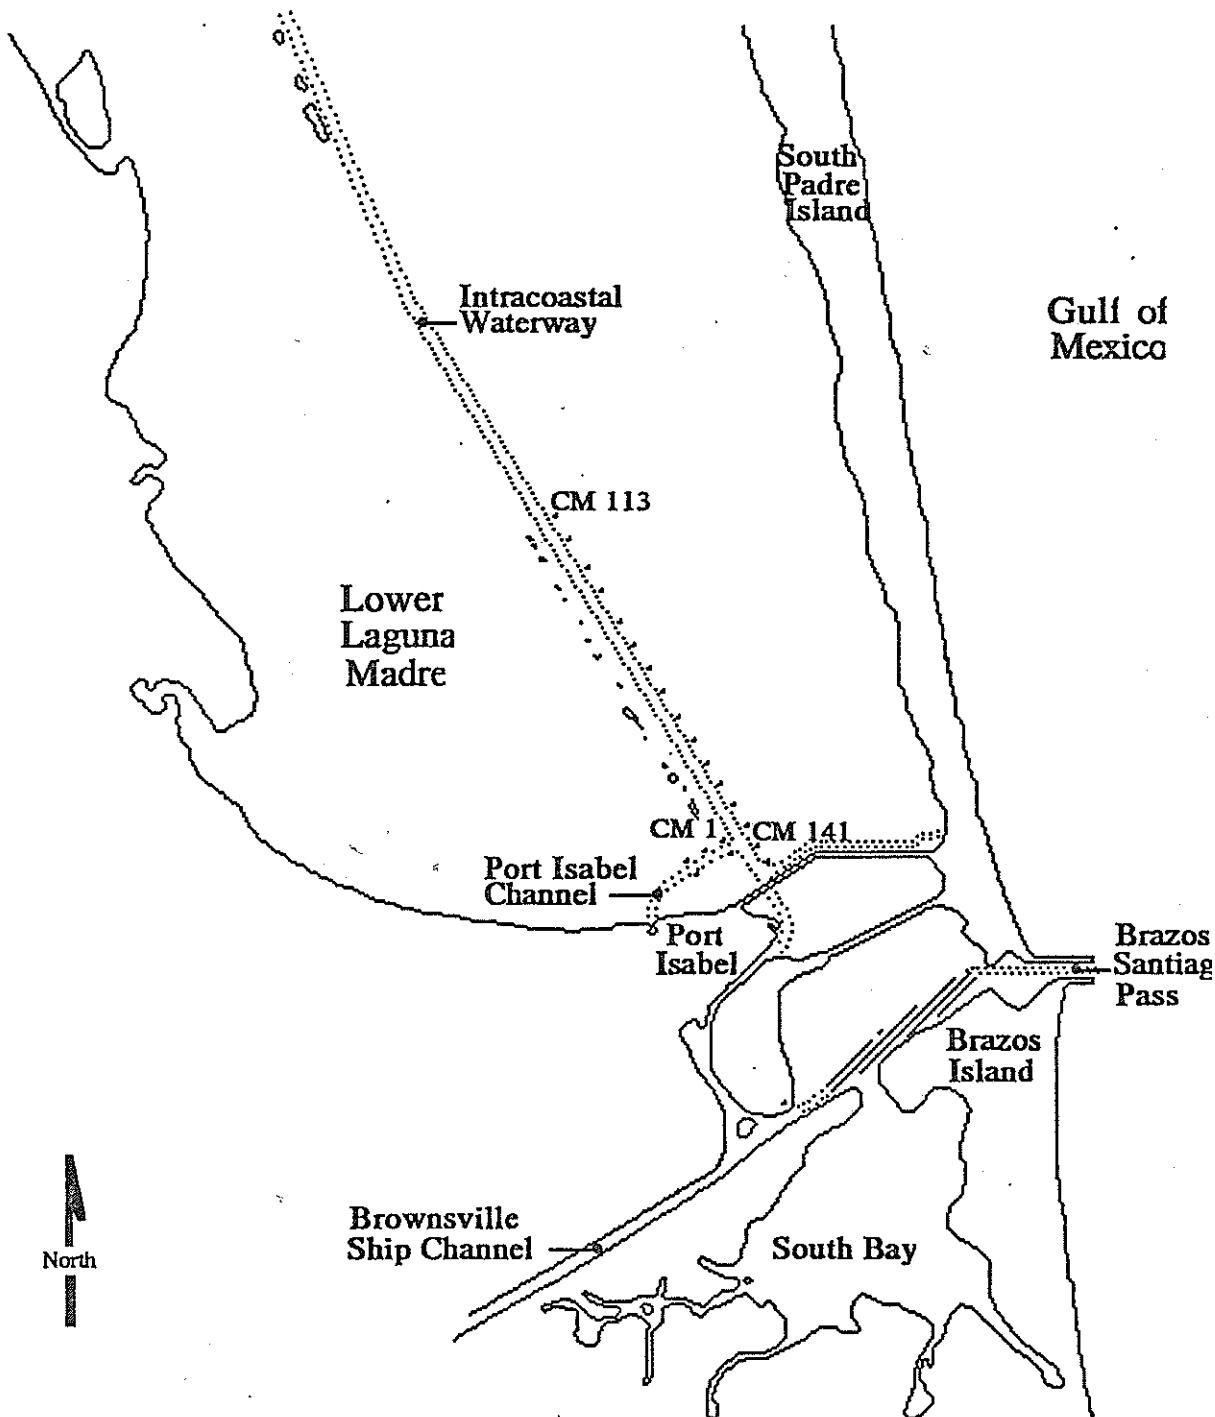

Figure 10. Areal extent of movement by a tagged (QQC 710, NNZ 611) 49.9 cm SCL green turtle (*Chelonia mydas*).

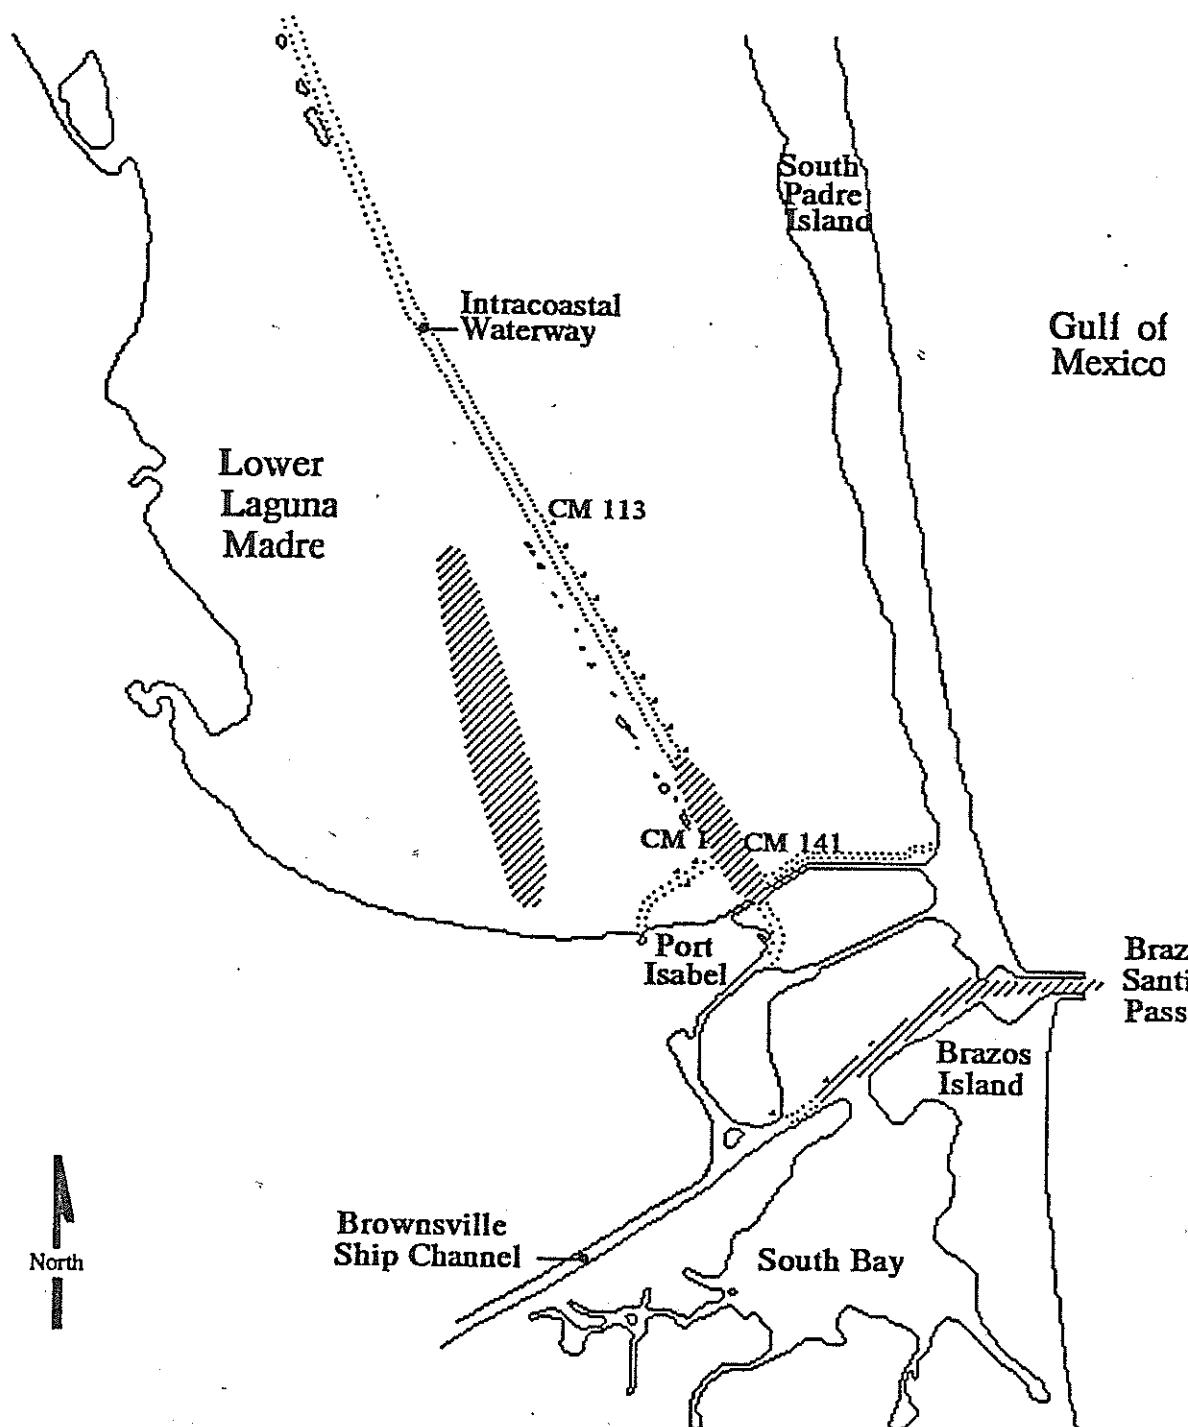

Figure 11. Areal extent of movement by a tagged (QQC 711, NNZ 753) 54.1 cm SCL green turtle (*Chelonia mydas*).

Brazos Santiago Pass Site - Jetty Description: The jetty habitat consisted of three distinct physical and biological zones. Physically, these zones differed in depth, bottom topography, and sediment type. Biological differences were evident in the concentrations and species diversity of the fouling communities (flora and fauna) and associated biota. The zones observed in all jetty habitats included:

Zone 1 - Partially exposed and submerged (≤ 3 m deep) granite builders with various species and concentrations of fouling organisms. The most dominant fouling species (listed in order of abundance) observed (Table 8) were barnacles (*Balanus* sp.), algae (*Ulva fasciata*, *Podina vickersiae*, *Bryocladia thysigera*), sea urchins (*Arbacia punctulata*) and oyster spat (*Ostrea equestris*). This zone extends 5 - 10 m away from the jetty proper with a depth range of 1.8 - 3.0 m. The greatest diversity and concentration of fouling organisms were observed within this zone.

Zone 2 - Scattered granite boulders (> 3 m deep) and rubble with a thin to moderate silt layer (increasing with depth). The abundance and diversity of the fouling organisms decreased from that in Zone 1 with the exception of oyster spat (the dominant species), stony coral (*Astrangia astreiformis*) and gorgonia (*Leptogorgia virgulata*). The sparse concentration of algae (particularly the filamentous alga *Ectocarpus siliculosus*) which occurred along the shallowest edge of this zone decreased with depth. This zone begins 6 - 15 m away from the jetty proper and is 5 - 10 m wide and 2 - 4.5 m deep. The greatest diversity of fishes was observed in this zone.

Table 8. Plant and encrusting taxa occurring in the South Padre Island study area during July - Octob

PIC - Port Isabel Channel Markers 1 and 2

D - dead representatives of these species

SB/MF - South Bay/Mexiquita Flats

Zone 3 - Little to no scattered rubble, flat barren bottom with varying amounts of silt and scattered oyster shell. With the exception of the coves, which were barren rippled sand, the silt layer depth ranged from moderate (≥ 1.0 cm) to very heavy (≥ 15.2 cm). This zone begins 10 - 25 m away from the jetty proper with a depth range of 2.1 - 7.5 m. No vegetation and very sparse biota (few hermit crabs, few scattered gorgonia) were observed in this zone. All stations within the Brazos Santiago Pass Site displayed this zonation with slight variations in depth, zone size and distance from the jetty proper. Differences in species diversity and abundance also were observed between stations. The vegetation diversity ranged from 14 species at Station 11 to three species at Station 25 (Table 8).

Brazos Santiago Pass Site - Trawl Survey: Channel habitat within Brazos Santiago Pass and immediately adjacent to the North and South Jetties was largely dominated by a varied ichthyofaunal assemblage (Tables 9 and 10 and Appendix Table 2). Four fish species, including Atlantic croaker (*Micropogonias undulatus* - 21.4%), pigfish (*Orthopristis chrysoptera* - 17.0%), pinfish (*Lagodon rhomboides* - 7.2%) and sand seatrout (*Cynoscion arenarius* - 6.9%), contributed over 52% of the total catch. Swimming crabs in the Family Portunidae were the only dominant invertebrate taxa (7.6%) at Brazos Santiago Pass channel habitats. The 42 taxa trawled from the two channel stations within this site represented species typically associated with reef structure [sea urchin (*Arbacia punctulata*), pigfish, red snapper (*Lutjanus campechanus*), barred grunt (*Conodon nobilis*), hunchback scorpionfish (*Scorpaena dispar*) and Atlantic spadefish (*Chaetodipterus faber*)] as well as demersal transients known to migrate

Table 9. Demersal taxa collected at trawl stations in the South Padre Island study area. Nomenclature follows that of Fotheringham and Brunenmeister (1989), Williams et al. (1989), and Robins et al. (1990).

<u>TAXON</u>	<u>COMMON NAME</u>
Unid. sponges	sponge
<u>Leptogorgia setacea</u>	sea whip
Unid. anemones	anemone
Unid. worms	worm
<u>Diopatra cuprea</u>	tube-building worm
Unid. snails	snail
<u>Cerithidea pliculosa</u>	horn shell
<u>Crepidula fornicate</u>	common Atlantic slipper shell
<u>Cantharus cancellarius</u>	cancellate cantharus
<u>Busycon sp.</u>	whelk
<u>Busycon perversum</u>	whelk
<u>Anachis semiplicata</u>	half-folded dove shell
F. Olividae	olive snail
<u>Bulla striata</u>	bubble shell
<u>Aplysia brasiliensis</u>	sea hare
Unid. bivalves	bivalve
<u>Anadra ovalis</u>	blood ark
<u>Noetia ponderosa</u>	ponderous ark
<u>Argopecten irradians amplicostatus</u>	bay scallop
<u>Ostrea equestris</u>	horse oyster
<u>Chione cancellata</u>	cross barred venus
<u>Loliguncula brevis</u>	bay squid
Unid. barnacles	barnacle
<u>Squilla empusa</u>	mantis shrimp
F. Isopoda	isopod
<u>Cymothoa excisa</u>

TOTAL	511	85.17	100.00

through channels [Atlantic guitarfish (*Rhinobatos lentiginosus*), Atlantic croaker, spot (*Leiostomus xanthurus*) and Atlantic cutlassfish (*Trichiurus lepturus*)]. Overall, catch per unit effort (CPUE) statistics for trawl tows ($n=6$) in channel habitats (85.2 organisms/tow) of Brazos Santiago Pass (Table 10) compared quite favorably with similar statistics from the lower Laguna Madre (78.0) and greatly surpassed that (27.0) from South Bay/Mexiquita Flats (Tables 11 and 12, respectively).

Barren hard-bottom habitats within the Brazos Santiago Pass site incorporated two cove stations (Station 16 - North Cove and Station 23 - South Cove) and three near-jetty stations (Stations 17 and 19-Gulf side of North Jetty; Station 25 - Gulf side of South Jetty) where fish, particularly spot (22.0%), pinfish (17.3%), and pigfish (11.7%), were dominant (Table 13). As with trawl catch statistics from the adjacent channel habitat, the only dominant invertebrates were a collective assemblage of swimming crabs in the Family Portunidae (4.7%). Except for a low species diversity along the Gulf side of the South Jetty (Station 25), species assemblages were rather similar across the barren-bottom habitats adjacent to Brazos Santiago Pass (Appendix Table 3) and reflected a mixture of organisms typically associated with channel and reef ecosystems. Overall, CPUE at barren-bottom stations was approximately half that at Brazos Santiago Pass channel stations while species diversity at these habitats was very similar (Tables 13 and 10, respectively, and Appendix Tables 3 and 2, respectively).

South Bay/Mexiquita Flats Site - Vegetation Analysis: Grassbed habitat within the South Bay/Mexiquita Flats site extended from the north side of the Brownsville ship Channel (BSC) across Mexiquita Flats (Fig. 12). Narrow grassbeds also run along the south side of the BSC

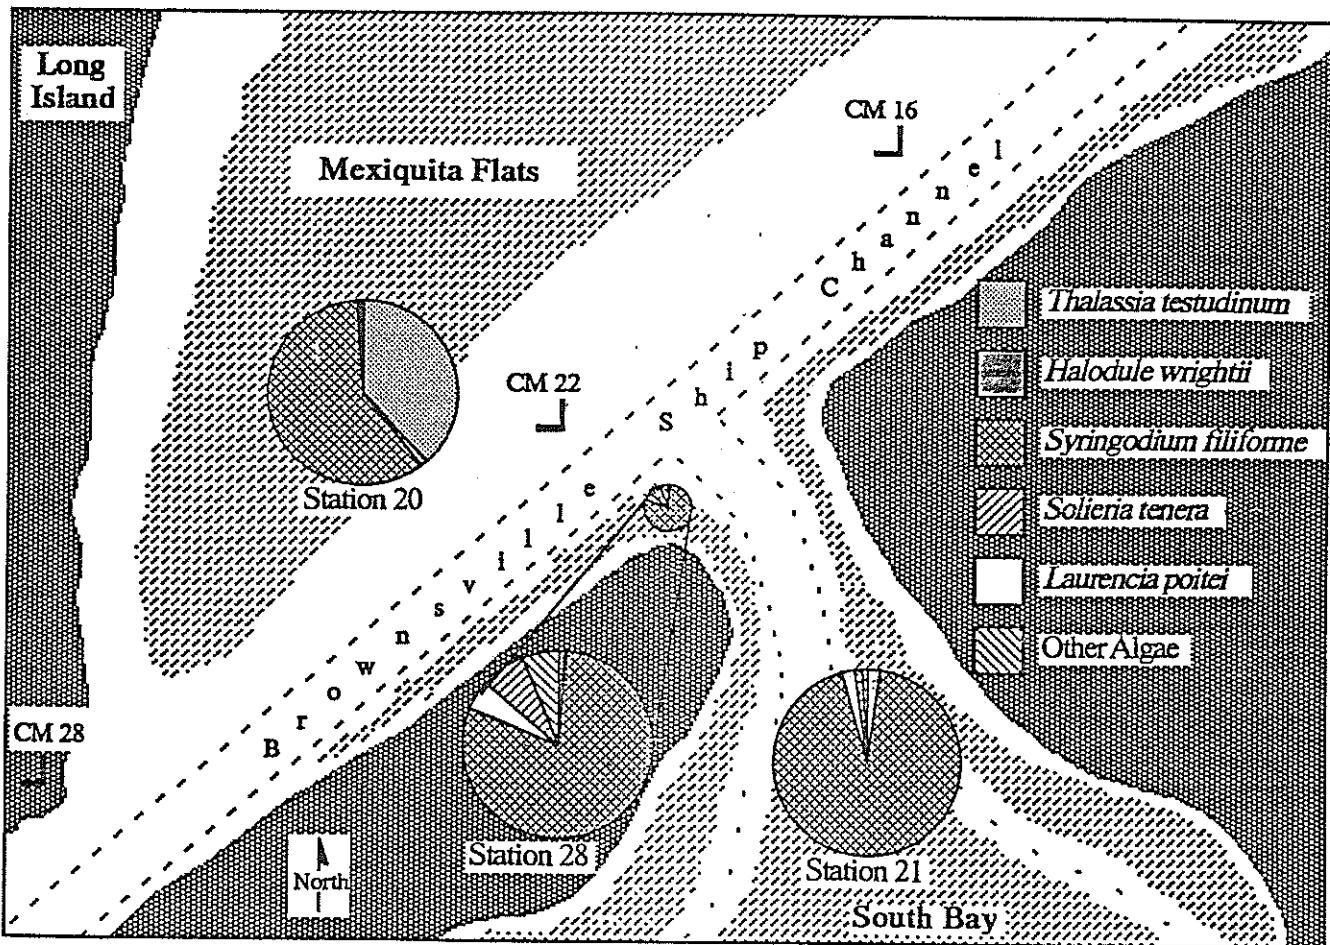

Figure 12. Dominant flora at South Bay/Mexiquita Flats grassbed stations.

and on both sides of the entrance channel into South Bay, where they expand into the bay proper. There are three grassbed stations at this site (Fig. 12): Station 20 lies to the north of the BSC between Channel Marker 22 and Long Island; Station 21 at the northernmost edge of South Bay grassbeds; and Station 28 at the northwestern edge of the entrance channel into South Bay.

Manatee grass (*Syringodium filiforme*) was the dominant sea grass species within grassbed habitats at South Bay/Mexiquita Flats stations (Fig. 12 and Appendix Table 4). Station 20 contained 61.65% manatee grass as well as large amounts of turtle grass (*Thalassia testudinum*, 36.10%), with very little shoal grass (*Halodule wrightii*, 1.11%) and traces of seven algal species (1.13%). Station 21 contained 93.32% manatee grass with a small amount of shoal grass (2.09%) and turtle grass (0.11%). Traces (3.48%) of four algae species also were found. Station 28 contained 79.52% manatee grass with traces of turtle grass and shoal grass, 1.05% and 0.69% respectively. This station had the greatest algal abundance, with 7.41% *Solieria tenera*, 5.08% *Laurencia poitei*, and 6.26% of nine other algae species.

Blade height statistics indicated that all three dominant sea grass species exhibited greatest growth at Station 28 (Fig. 13). Sea grass development at Stations 20 and 21 varied with species (Appendix Table 5).

The physical arrangement of constituent sea grass and algal species was fairly consistent among South Bay/Mexiquita Flat stations. Sea grasses were randomly intermixed with algae including *Dictyota dichotoma*, *L. poitei*, *Hypnea musciformis*, *S. tenera*, *Corallina cubensis*, *Spyridia filamentosa*, *Chondria littoralis*, and *Gracilaria foliifera*. Algal species often were attached to, or wrapped around, seagrass blades. *Sargassum* spp. were found laying across

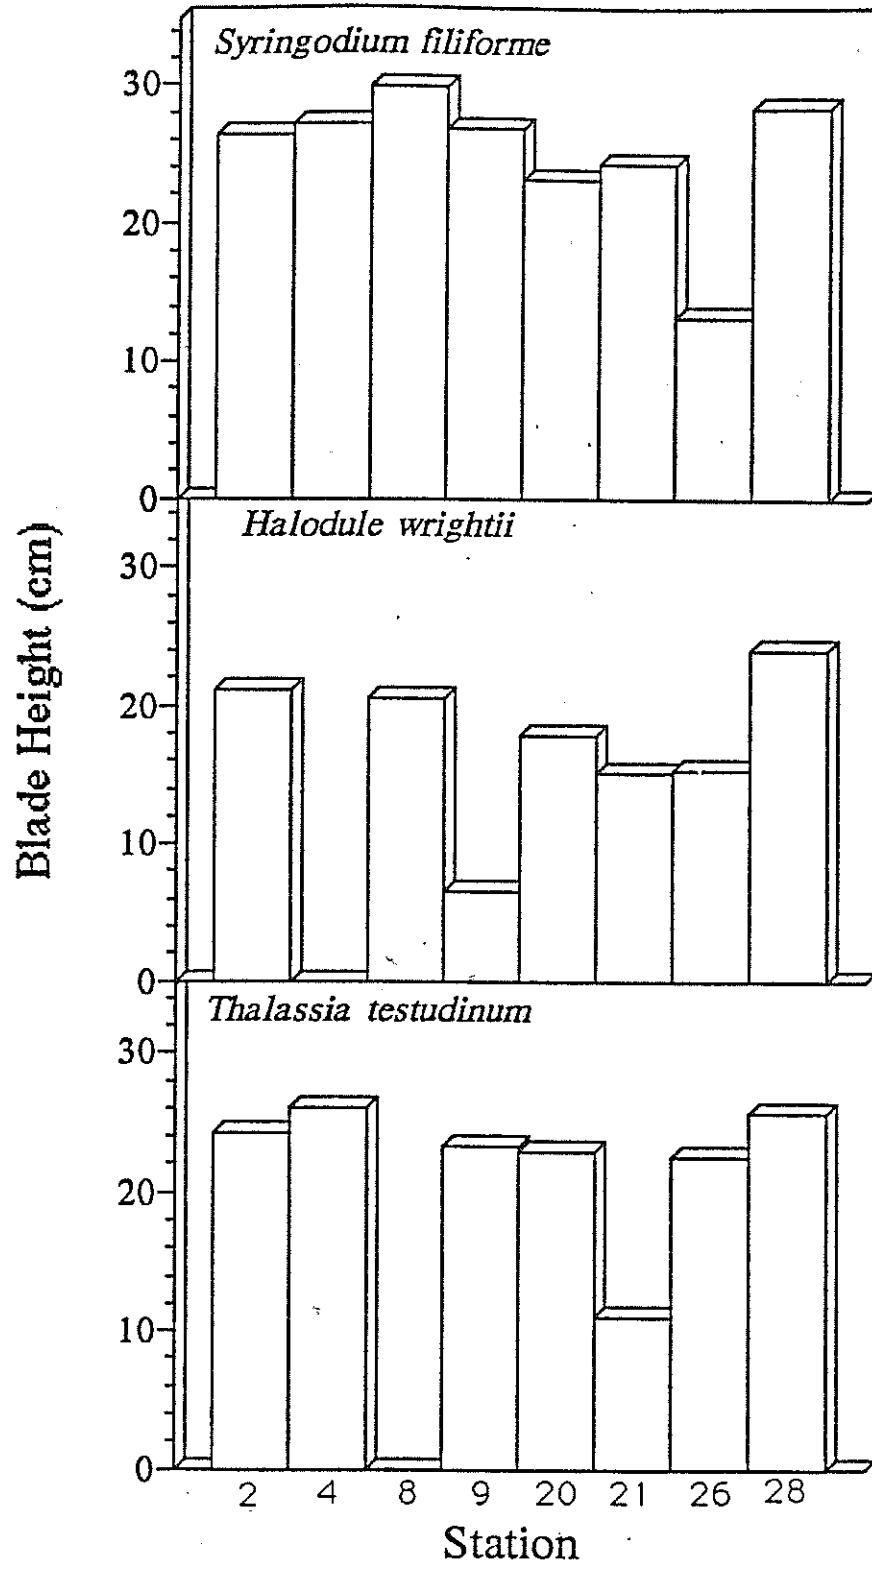

Figure 13. Blade height (cm) of dominant seagrass species at grassbed stations.

grassbeds, and the aquatic plant *Halophila engelmannii* was occasionally observed growing among sea grasses. In all cases where the bryozoan *Bugula neritina* was encountered in grassbed habitat, it was found to be epiphytic on seagrass blades.

South Bay/Mexiquita Flats Site - Trawl Survey: South Bay/Mexiquita Flats was a relatively small, well-confined site with grassbed, barren-bottom and channel habitats in close proximity to one another (Fig. 3). For this reason, only five trawl stations (20, 21 and 28 - grassbed; 15 - barren-bottom; 22 - channel) were deployed at this site. Grassbed, barren-bottom and channel habitats ranked first, second and third, respectively, in CPUE and number of species statistics at the South Bay/Mexiquita Flats site (Tables 14, 15 and 12). The 52 assorted taxa caught in grassbed trawls (Table 14 and Appendix Table 6) were dominated by pinfish (43.7%) and, to a lesser degree, the arrow shrimp (*Tozeuma carolinense* - 12.4%). All other dominant taxa were invertebrates (primarily shrimp in the genus *Penaeus* or *Hippolyte*) with percent contributions to the total catch \leq 6.5%. Nevertheless, the grassbed faunal community at this site was distinguished by a wide array of invertebrate taxa, whose diversity (Appendix Table 6) rivaled that of lower Laguna Madre grassbeds. One exception to these similarities in invertebrate diversity was the failure of South Bay/Mexiquita Flats grassbeds to yield blue crab (*Callinectes sapidus*) abundances comparable to those in the lower Laguna Madre (Tables 14 and 16).

Barren-bottom (Station 15) and channel habitats (Station 22) within the South Bay/Mexiquita Flats site exhibited faunal communities similar to those in grassbed habitat (Tables 13, 12 and 14, respectively). Barren-bottom provided prime habitat for four dominant demersal taxa - pinfish (34.1%), pigfish (11.4%), aggie mojarra (*Eucinostomus harengulus* -

Table 14. Dominant ($\geq 2\%$ of total catch) taxa in trawl tows at South Bay/Mexiquita Flats grassbed stations (20,21,28) during July-September 1991.

* Those taxa comprising $\geq 2\%$ of total catch after the deletion of *Anchoa mitchilli* (633 individuals).

10.4%) and *Callinectes* sp (12.9%) - which collectively contributed nearly 70% of the total catch (Table 13). Although much reduced, catches from the channel habitat community were taxonomically similar to those at barren-bottom habitat, with the spotfin mojarra (*Eucinostomus argenteus* - 38.3%) and blue crab (12.4%) comprising over 50% of the demersal population (Appendix Tables 2 and 3).

Lower Laguna Madre Site - Vegetation Analysis: Grassbed habitat within the lower Laguna Madre site extended north from the Queen Isabella Causeway between the Intracoastal Waterway IWW and South Padre Island (Fig. 4). Another grassbed immediately west of the IWW extended north from just above Port Isabel Channel and beyond Channel Marker 113. Smaller grassbeds were located west of IWW Channel Marker 135 at Walt's Bar and southwest of the intersection of the IWW and Port Isabel Channel.

Five grassbed stations were located at this site (Fig. 14): Station 2 in the westernmost portion of the grassbed covering Walt's Bar; Station 4 was 1.6 km east of the IWW between Channel Markers 131 and 133; Station 8 was 100 m southwest of Port Isabel Channel Marker 1; Station 9 was 600 m east of IWW Channel Marker 135; and Station 26 was 0.5 km west of IWW Channel Marker 135.

Turtle grass, was the dominant sea grass species across the lower Laguna Madre site (Fig. 14 and Appendix Table 4). Station 2 contained 48.42% turtle grass with 20.88% manatee grass and 14.32% shoal grass. There were also significant amounts of the algae *S. tenera* and *L. poitei*, 6.99% and 5.03% respectively. Seven other algal species made up the remaining 4.34%. Station 9 contained 56.62% turtle grass with 19.81% manatee grass and almost no shoal

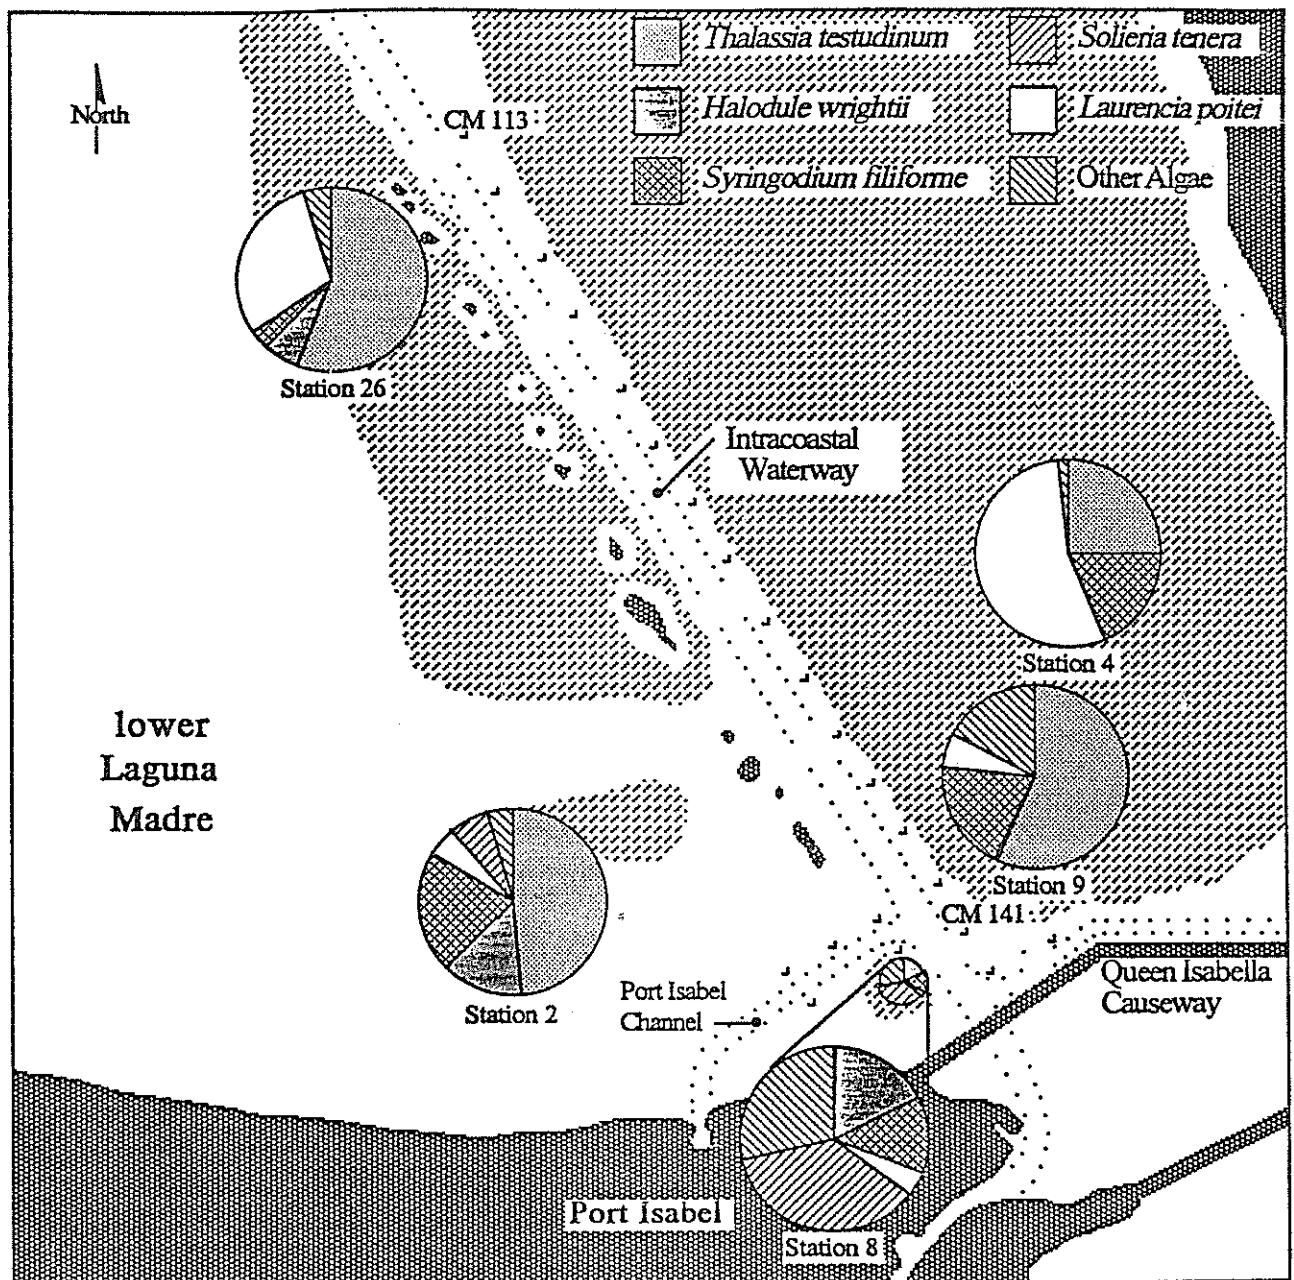

Figure 14. Dominant flora at lower Laguna Madre grassbed stations.

grass (0.24%). There was also a great abundance of the algae *H. musciformis* (15.69%) and *L. poitei* (5.76%). Two other algal species made up the remaining 1.88%. Station 26 contained 55.52% turtle grass with lesser amounts of shoal grass and manatee grass, 6.69% and 3.12% respectively. *L. poitei* made up 29.80% of the vegetative biomass and three other algae made up the remaining 4.87%. The grassbed habitats at Stations 4 and 8 were dominated by algal species. Station 4 contained 54.67% *L. poitei* and 1.81% of two other algae. Turtle grass and manatee grass also had a strong presence here, making up 24.90% and 18.62% of the vegetative biomass, respectively. Station 8 was dominated by *S. tenera* (36.07%) with another 15.29% made up of *C. cubensis*. Seven other algae made up another 17.67%. Shoal grass was the dominant sea grass species (17.10%) with 13.29% manatee grass and very little turtle grass (0.58%).

Blade height statistics indicated fluctuating development of all sea grass species across all of the stations (Fig. 13). The physical arrangement of the various sea grasses and algae was similar to that found in the South Bay/Mexiquita Flats site.

Lower Laguna Madre Site - Trawl Survey: Trawl tows ($n=33$) at six lower Laguna Madre stations (3, 5, 6, 7, 13 and 18) in IWW channel habitat produced 89 demersal taxa comprised of 33,668 organisms (Appendix Table 2), 92.5% (31,095 individuals) of which were bay anchovy (*Anchoa mitchilli*). Anchovy abundance statistics greatly overshadowed those of other inhabitants of the IWW and were misleading since 97% of this species' total was taken at one station (6). Consequently, bay anchovies were deleted from trawl catches at IWW stations in an effort to better define the contribution of constituent taxa to channel communities (Table 11).

This deletion resulted in channel communities being dominated (65.1% of revised catch totals) by seven taxa - four invertebrates [bay squid (*Loliguncula brevis*) 6.8%; net-clinger shrimp (*Acetes americanus* -7.5%) false zostera shrimp (*Hippolyte pleuracantha* - 13.7%) blue crabs (17.9%) and three fishes (aggie mojarra - 5.8%; pinfish - 7.0%; Atlantic croaker - 6.4%). Although the lower Laguna Madre site contained a larger number of sampling stations and received more trawling effort, channel habitat in this site probably exhibited a greater diversity and abundance of demersal taxa than that in similar habitats at Brazos Santiago Pass and South Bay/Mexiquita Flats sites (Tables 11, 10 and 12, respectively). This was particularly true for invertebrate taxa including squid, and penaeid shrimp and portunid swimming crabs which are common food sources for the loggerhead sea turtle. Occupation of the six IWW stations by the loggerhead during summer months (Fig. 7) was concurrent with moderate to high abundance of bay squid, penaeid shrimp, callinectid crabs and demersal fish species whose size made these species an attractive food item.

Barren-bottom stations in the lower Laguna Madre incorporated three hard-bottom (Stations 1, 14 and 27) and two dredge-spoil (Stations 10 and 12) habitats which collectively ($n=21$ tows) produced 49 demersal taxa comprised of 4271 individuals (Table 17). The demersal community at barren-bottom habitats resembled that in the IWW. The bay anchovy, due to large abundance of this schooling species at station 1, accounted for 67.9% of the total catch over barren-bottom habitat (Table 17). Deleting the bay anchovy from barren-bottom catches resulted in blue crab (16.4%), pigfish (13.7%) and pinfish (22.3%) representing over half (52.4%) of revised faunal totals for this habitat. Other dominant species known to be food sources for the loggerhead which occupied at least three barren-bottom stations during summer

Table 17. Dominant* taxa in trawl tows at Lower Laguna Madre barren-bottom stations (1,10,12,14,27) during July-September 1991.

TOTAL	1371	65.29	100.00

* Those taxa comprising $\geq 2\%$ of total catch after the deletion of *Anchoa mitchilli* (2900 individuals).

months included bay squid (2.1%) and brown shrimp (*Penaeus aztecus* - 3.1%). Station 1, the loggerhead capture site, yielded the highest CPUE (with and without anchovy abundance included), a wide assortment of invertebrate and fish taxa, and modest abundances of potential loggerhead food sources, including squid, blue crabs and other portunid swimming crabs (Appendix Table 3). Other notable findings within barren-bottom habitats were the diverse demersal communities at active dredge spoil sites (Stations 10 and 12) frequented by the loggerhead (Appendix Table 3 and Fig. 7). Catches at these stations included sizeable percentages of potential loggerhead food items such as blue crabs (5.9% to 30.6%) and brown shrimp (3.0 to 7.1%). Collectively, barren-bottom habitats at the lower Laguna Madre site produced trawl catches which compared favorably with those from similar habitat at Brazos Santiago Pass and South Bay/Mexiquita Flats sites (Appendix Tables 3).

Trawl tows (27) at the five lower Laguna Madre grassbed stations (2, 4, 8, 9 and 26) produced 73 taxa comprised of 4139 individuals (Table 16). As with catches from channel and barren bottom habitats, bay anchovy (1372 individuals) dominated (33.1%) grassbed communities (Table 16 and Appendix Table 6). Other dominant taxa, after omission of bay anchovy, included pinfish (26.9%), three other less abundant fish species (collectively 12.1%) and a much broader array of dominant invertebrate taxa than was taken at channel and barren-bottom habitats with the lower Laguna Madre site (Tables 16, 11 and 17, respectively). Prominent among dominant invertebrate taxa were species such as brown shrimp (2.4%), blue crabs (7.3%) and xanthid mud crabs (5.8%) that represent potential food items for the loggerhead which frequented grassbed habitats (Stations 4, 8 and 9) immediately adjacent to the IWW channel environs. A comparison of dominant taxa at lower Laguna Madre grassbed

stations with those from South Bay/Mexiquita Flats (Tables 16 and 14, respectively) revealed invertebrates comprising larger percent of trawl catches at the former site while pinfish abundance greatly overshadowed that for other taxa from the latter site.

Fecal Pellet Analysis: Fecal samples obtained from 18 green turtles contained minute pieces of algae and/or sea grass in a partially digested state (Table 18). Advanced digestion prevented algae from being identified to species. Sea grasses also were unidentifiable for the most part, except that about 20% of the epidermal tissue layers exhibited a speckling characteristic of manatee grass.

Earliest fecal pellet analyses were conducted on four green turtles captured at the Brazos Santiago Pass site between April and July (Table 18). Fecal contents of these turtles were similar, consisting mostly of algae with one sample containing an insect wing and an intact hydroid *Obelia*. Only one of four turtles from the Brazos Santiago Pass exhibited sea grass in its fecal contents. The remaining 14 fecal samples analyzed after July came from 12 turtles captured at the South Bay/Mexiquita Flats site and 2 incidental captures at the Brazos Santiago Pass site. All of these fecal contents were dominated by sea grasses, with traces of algae found occasionally. Also noted among these contents were an intact hydroid *Obelia* from one turtle and unidentified minute eggcasings found intact in six fecal samples.

Table 18. Fecal contents of green sea turtles (*Chelonia mydas*) captured in the South Padre Island study area during April - November 1991.

Discussion

Sea Turtle Capture

Capture statistics from this study indicate that entanglement netting was a reasonably effective method of catching sea turtles in the South Padre Island study area. Seventeen of 19 turtles captured during the study were taken in entanglement nets. These turtles exhibited a wide range of sizes (i.e., a 26.0-cm SCL green and a 72.5-cm SCL loggerhead) and were captured across a variety of jetty, channel and grassbed habitats, each with a unique array of environmental traits.

Deploying entanglement nets of different mesh sizes and depths facilitated capture of sea turtles across a wider array of habitats in the study area. Each entanglement net design demonstrated an ability to capture turtles. Shallow, small-mesh nets (3.7 m deep with 12.7-cm bar mesh) produced five turtles in 37 nets sets and were particularly effective in capturing the younger turtles inhabiting jetty environs. Small-mesh nets also tended to foul less frequently on jetty rocks, and when fouled with vegetation, were effectively cleaned with a change in tides. Deployment and sampling efficiency of shallow, small-mesh nets became more restricted with an increase in water depth and current speed. Deeper, large-mesh nets (4.9 m deep with 25.4-cm bar mesh) yielded 12 turtles in 53 net sets. These larger nets, although less effective in jetty habitats, were less restricted by depth and current, produced a smaller volume of by-catch and were probably less visible to potential prey.

Numerous sightings of turtles near the North and South Jetties at Brazos Santiago Pass accentuated the importance of jetties as a turtle capture site. However, capture success at the

jetties was compromised by this habitat's rugged physical setting. This dilemma could be solved by deploying turtle encirclement techniques with nets modified to negate depth restrictions and bottom obstructions. Increasing the depth of the small-mesh net design to 7.4 m and adding chafing gear along the leadline is one modification that will be evaluated at jetty environs during Summer 1992.

Habitat Utilization

The South Padre Island study area provided a variety of habitats suitable for utilization by green and loggerhead turtles. Capture of turtles in nets deployed at the Brazos Santiago Pass site as well as numerous sea turtle sightings at this site from April through November were indicative of the Pass' role as a major corridor to an array of habitats frequented by turtle species. Three habitats - jetty, channel and grassbed - were utilized in one fashion or another by green and loggerhead turtles.

TAMU's netting results and turtle sightings combined with NMFS' tracking data indicate that jetty and Brazos Santiago Pass environs were a primary habitat for green turtles. The jetty, with its varied array of attached algae species and crevices, may have provided a food source and refuge for younger greens frequently seen at this site. Numerous sightings of younger green turtles within Brazos Santiago Pass habitats throughout the study period and the strong site fidelity shown by one small radio/sonic tagged green (tag #'s QQC707/NNZ612) certainly suggest that jetty environs are important to younger cohorts of this species. Visual observations indicated this turtle remained along the Gulf side of the North Jetty long after the battery life of its tag expired. In addition, the size of green turtles captured and observed within Brazos

Santiago Pass habitats was much less than that of turtles from South Bay/Mexiquita Flats and lower Laguna Madre sites. Analyses of fecal pellets from greens captured at jetty habitats provided limited information on feeding habits. However, these analyses did indicate the possibility of young greens grazing on algae found at the jetties. In addition to using jetties as a feeding ground, green turtles exhibited a propensity for occurring at specific sites along the jetties. The radio- and sonic-tagged green turtle commonly seen at the North Jetty throughout the study was almost always sighted along a confined, near-jetty zone between Stations 17 and 19. This behavior may indicate that jetties provide young greens with refuge or a seasonal residence as well as a foraging area.

Capture data and/or NMFS' tracking results indicate that larger greens preferred grassbed habitats of South Bay/Mexiquita Flats and lower Laguna Madre sites over jetty habitats at the Brazos Santiago Pass site. The fact that all green turtles netted in grassbeds were noticeably larger than other smaller cohorts netted and frequently sighted at Brazos Santiago Pass habitats may indicate a segregation of the green sea turtle community by habitat and/or feeding preference. Turtles initially captured in grassbed habitats generally returned to these sites after being tagged. These turtles also tended to exhibit a wider range of movement than greens at the jetty, with this movement restricted to grassbed habitats. This "habitat fidelity", combined with fecal pellet analyses that indicate larger greens fed on sea grasses, support a theory of foraging-related partitioning of habitats within the study area by turtle size or feeding ability. The well developed grassbeds found throughout South Bay/Mexiquita Flats and lower Laguna Madre sites are typical of green turtle feeding grounds documented by numerous other studies.

Channel environs of the lower Laguna Madre were a preferred habitat for the only loggerhead captured during the study. This habitat, particularly that within the IWW between Channel Markers 119 and 141, harbored sizeable abundances of portunid swimming crabs, especially the blue crab. These high crab abundances and sizeable quantities of other possible loggerhead food items such as squid, penaeid shrimp and various demersal fish species made channel environs an attractive feeding grounds. The loggerhead would occasionally venture into adjacent grassbeds where crab abundances also were high. NMFS' data indicate that the loggerhead largely remained in the lower Laguna Madre site throughout the tracking period. Failure of this species to occupy channel habitats within Brazos Santiago Pass and South Bay/Mexiquita Flats sites may have resulted from reduced invertebrate abundances at these sites.

Extensive use of habitats within the South Padre Island study area by sea turtles precipitated some concern about potential impact to these communities from COE dredging operations. Maintenance dredging of the IWW channel and Brazos Santiago Pass poses a direct threat to species such as loggerhead and green turtles which use these habitats as foraging and/or refuge areas. Dredging activities represent a risk to these species through suction of turtles into intake-water ports and destruction of foraging grounds. Despite these concerns dredging operations along reaches of the IWW within the study area during a 2-week period in July did not appear to influence loggerhead movement and/or utilization of channel habitats. In addition, trawl samples taken at two active dredge spoil sites (Stations 10 and 12) yielded a varied assemblage of demersal organisms.

Additional investigations are needed to better define sea turtle dependence upon and utilization of habitats within the South Padre Island study area and to assess potential impacts

to these communities by COE dredging operations. Recommendations specific to these investigations include the following:

1. Seasonal Occurrence - The TAMU and NMFS studies provide considerable information on sea turtle occurrence and habitat utilization during summer and fall months. Similar monitoring efforts should be expended during winter and spring months to assess the possibility of turtles "overwintering" in the study area and to define those periods of reduced turtle abundance that could be scheduled for dredging operations. Use of longer-lived batteries in NMFS' tags would expand the length of time turtles could be tracked and, as such, provide a wider array of data on seasonal occurrence in the study area.
2. Habitat Utilization - Brazos Santiago Pass and South Bay/Mexiquita Flats sites received over 86% of the netting effort during the present study. An increased capture effort should be expended in the lower Laguna Madre site due to the potential attraction of sea turtles to its rich seagrass and channel habitats. The limited netting effort conducted in lower Laguna Madre prevented a true characterization of sea turtle occurrence in this site and compromised an assessment of impact to these turtles from COE dredging operations.
3. Feeding Ecology - Although two green turtles were sighted grazing on algae in the intertidal zone of the North Jetty, visual observations of most turtles feeding in the study area were difficult to make due to poor water clarity and the cryptic behavior of turtles. Furthermore, fecal pellet analyses provided limited insight to sea turtle feeding ecology. A more detailed cellular examination than that deployed during the present study is needed to improve taxonomic identification of seagrass and algae species. An analysis

of caloric content and nutritional value of dominant seagrass and algae species is needed to better define the role that jetty and grassbed habitats play in feeding ecology of green turtles in the study area.
